I only have two drinking water fountains in my building? Do I still have to take the required number of samples?

If you have fewer drinking water fixtures than the chart requires, sample the ones you have and note on the sample log sheet you have sampled all drinking water fixtures.

We operate a large facility with multiple buildings and numerous drinking water fixtures. How many and where to do we sample from?

Sample the drinking water fixtures in the building up to the chart number based on the population of your facility. For instance, if your building has eight drinking water fixtures, and you are required to take five samples, sample only five of the fixtures. If you have more than the chart number of drinking water fixtures, select ones that represent the water distribution system, i.e. one in each building wing or on each floor. For large facilities collect at least one sample per building until you get the number of samples required in Table 1. Or, you can collect more than the minimum number of samples. If you have only a few buildings, split the samples among them as best you can according to where the water is being consumed.

SAMPLING PROTOCOL

- Obtain sample containers and analysis from a laboratory certified by the MDEQ for lead/copper analysis.

- Collect **FIRST DRAW** samples. (Water has stood motionless in the piping for at 6 hours.) **DO NOT SAMPLE AFTER WEEKENDS, HOLIDAYS OR EXTENDED PERIODS OF STAGNATION. Do not flush the sample tap before sample collection.**

- **Collect samples where water is drawn primarily for drinking. Sample drinking fountains, or kitchen/break room faucets if they are used routinely to obtain water for consumption.** Do not sample from mop sinks, hose bibbs, etc.

City of Flint Drinking Water
Outline prepared by the
Michigan Department of Environmental Quality for the
Flint Water Task Force

I. INTRODUCTION

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), with respect to events in the city of Flint (City), Michigan.

II. BACKGROUND

1. How has Flint historically obtained its drinking water?

The water system in the City was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City. In 1967, the City switched and became a customer of the Detroit Water and Sewerage Department (DWSD) system.

After the switch to DWSD, the City operated their water treatment plant as a standby plant for purposes of reliability in the event of an emergency such as an interruption in service through the single pipeline from DWSD.

During 2009, the water treatment plant was used in an emergency capacity in two instances: June 18 through June 20 and September 10 through September 13. Additionally, as a backup emergency plant, the City was required to operate the plant quarterly to demonstrate the capability to produce safe water in accordance with Act 399 and to keep mechanical equipment (such as valves, rubber seals, etc.) in good working order. Each quarter the plant was test run, samples were taken of both raw water and of finished water (post-filters). Monitoring showed that the WTP was performing as designed. However, as a result of contractual obligations with DWSD, this treated water was not put into the City's distribution system during these test runs, but rather was discharged to the river in accordance with a National Pollutant Discharge Elimination System (NPDES) Permit. The test runs were for demonstration purposes, to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules exist to ensure safe drinking water is provided to City residents?

The federal Safe Drinking Water Act (federal SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the federal SDWA, the United States Environmental Protection Agency (USEPA) sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and

1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (The federal SDWA does not regulate private wells which serve fewer than 25 individuals.)

Originally, the federal SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to the USEPA for "primacy," the authority to implement the federal SDWA within their jurisdictions, if they will adopt standards at least as stringent as the USEPA's and enforce those standards. Michigan adopted the Safe Drinking Water Act in 1976 through Act 399 and has maintained primacy for the program since that time.

3. **What is the USEPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the federal SDWA, the USEPA is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards, by working with states.

Michigan's drinking water program is audited annually by the USEPA for compliance with the federal SDWA. Based upon these audits, the USEPA continues to find Michigan's drinking water program to be compliant with the federal SDWA.

4. **What is the Michigan Department of Environmental Quality's (DEQ) role as a regulatory agency in implementing the SDWA?**

The federal SDWA permits states to accept oversight of the drinking water program under an agreement with the USEPA giving states primary enforcement responsibilities (or primacy). In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes. Michigan has had regulatory authority providing oversight of public water supplies since 1913 (waterworks and sewerage systems Act 98 of 1913).

The DEQ has been granted primary enforcement authority in Michigan for the federal SDWA under the legislative authority of Act 399. As such, the DEQ, Office of Drinking Water and Municipal Assistance (ODWMA) has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies. A community water supply provides year-round service to 15 or more living units or 25 or more residents. A noncommunity water supply has 15 or more service connections or serves 25 or more individuals on an average daily basis for not less than 60 days per year.

The DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: conducting surveillance visits at water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the training, examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; and since 1996, providing financial assistance for system improvements.

5. What is the City's role in implementing the federal SDWA?

State and federal programs develop regulations and perform oversight and compliance activities, but do not treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers in compliance with state and federal regulations.

To ensure that drinking water is safe, the federal SDWA sets up multiple barriers against pollution. These barriers include: source water protection, multiple treatment components, distribution system integrity, proper operations oversight, and public information. As a public water system, the City is responsible for ensuring proper design, construction, operations and maintenance, so that contaminants in tap water do not exceed the standards established by law. The City treats the water, and must test their water frequently for specified contaminants and report the results to the DEQ. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The federal SDWA recognizes that customers have the right to know what is in their drinking water and where it comes from. The City, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports (CCR) on the source and quality of their tap water.

The City submits samples of their water for laboratory testing (monitoring) to verify the water they provide to residents meets all federal and state standards. How often and where samples are taken varies from system to system and from contaminant to contaminant. The DEQ provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the City is required to employ properly, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the City's water system.

III. THE FLINT RIVER – IS IT A SAFE SOURCE OF DRINKING WATER?

In Michigan, we are fortunate to have high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, the majority of which is withdrawn from the Great Lakes. A handful of public water supplies in Michigan do treat water from inland rivers, lakes or groundwater under the influence of

surface water. All surface water sources and groundwater under the influence of surface water requires significant treatment in order to be safe for consumption. Treatment of surface water is referred to under Act 399 as "complete treatment."

While all surface water sources must receive this higher level of treatment, river sources present a greater challenge than water withdrawn from one of the Great Lakes. River sources are more challenging to treat because of how rapidly water quality may change compared to Great Lakes Sources. Under most circumstances, rivers are also prone to greater fluctuations in temperature, have higher amounts of organic material, greater turbidity (suspended solids), and are more vulnerable to microbiological and viral contamination than Lakes Huron, Erie, Michigan or Superior. It should be noted, that while the water chemistry in the Flint River differs from that in Lake Huron, it can still be treated in accordance with the federal SDWA and Act 399. Many cities across the country rely on similar sources for drinking water. The waterworks industry has the technology to treat wide ranging source waters to provide potable and palatable drinking water, including direct reuse of wastewater. Regardless of source water quality, all public water systems must comply with the same drinking water standards in the finished water.

Also, it is not the source water that reacts with the homeowners plumbing out in the distribution system, but rather the finished water quality that is important. To begin with, neither the Flint River nor the treated water leaving the City's WTP contains lead. In addition, the treatment process employed by the City includes lime softening to reduce the hardness in the river water. Lime softening is not a process that would typically be thought to increase corrosivity of water. The City, however, does practice recarbonation to readjust pH at the end of the softening process. pH levels of finished water leaving the City's WTP averaged 7.7. Water monitoring conducted quarterly at 25 sample sites located throughout the distribution system showed the following:

July – September 2014	average pH = 7.71	range: 7.56 – 7.86
October – December 2014	average pH = 7.88	range: 7.62 – 8.10
January – March 2015	average pH = 7.81	range: 7.60 – 7.99
April – June 2015	average pH = 7.63	range: 7.48 – 7.80

The following data was obtained at the same sampling locations throughout the City's distribution system, but while they were still purchasing water from DWSD before the City switched to the River as a source:

January – March 2014 (DWSD)	average pH = 7.47	range: 7.40 – 7.54
April 2014 (DWSD)	average pH = 7.49	range: 7.42 – 7.59

Note that the pH numbers while the City was treating the Flint River did not differ significantly from those produced by DWSD, and in fact, tended to be slightly higher (less corrosive).

IV. *E. COLI* AND TOTAL COLIFORM BACTERIA VIOLATIONS

1. **What caused the *E.Coli* and total coliform bacteria violations experienced by the City in August and September 2014?**

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWAs) in the City during August and September 2014 triggered by exceedances of bacteria standards in limited areas of the distribution system. While the Flint River has higher levels of natural organic matter than typically found in the Great Lakes, Flint's water treatment plant (WTP) performed well above requirements for removal of organic carbon. In addition, the coliform detections were confined to less than 20 percent of the water system. If treatment had been compromised, detections would have been expected throughout the City rather than in such a limited geographic area.

Instead, the violations seem to have been caused by other factors such as aging infrastructure and unusual weather patterns. The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of unlined cast iron piping. This cast iron pipe is subject to internal corrosion, called tuberculation, which thins and weakens the pipe walls in some areas and causes a buildup of sediment and debris on the pipe walls in other areas. Tuberculation can lead to water quality issues as well as reduced flows and pressures. Tuberculation also encourages the development of biofilms, or layers of bacteria that attach to the rough surfaces of interior pipe walls. Biofilm growth is common in areas where little or no disinfectant residual is maintained, and together with tuberculation, may clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining customer base and water use, with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time (stagnation) within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and loss of disinfectant residual. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been known to improperly use fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination. These hydraulic disturbances were also believed to be the source of the aesthetic water quality complaints both the city and DEQ were receiving.

The winter of 2013/2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30 percent, saw even greater losses since February of that year due to an increase in cold weather related water main breaks and leaks (400 water main breaks in calendar year 2014, with greater than 50 percent in the winter quarter). The City has also been lacking a formal maintenance program for its more than 7,250 valves, which are critical in limiting the areas impacted during water main repairs. As an example, two valves on the transmission line used to supply the area of the 2014 BWAs were found to be closed during the City's investigation of possible sources, causing much longer residence times, reduced disinfectant residuals, and reduced pressures – all potential avenues for contamination to enter a distribution system.

The BWAs also occurred during the warmest and relatively wet periods of August and September 2014. Warm weather conditions are not only more conducive to bacterial

growth but also degrade disinfectant residuals more quickly. As already explained, longer residence times, biofilms, and tuberculation contribute to disinfectant residual degradation. Warm, wet weather conditions also allow water contaminated with bacteria to accumulate or pond around piping that leaks and breaks.

During the summer of 2014, the city was actively repairing the distribution system (29 water main breaks in June through August 2014). After the switch to the Flint River, it was discovered that there were many broken or closed valves in the distribution system (120 broken valves and 239 valves in an improper position). As the city began correcting this problem they did detect the presence of coliform organisms in the distribution system in the testing conducted as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected? What was the DEQ's response?

Federal SDWA Regulations regarding monitoring and standards for bacteria in water distribution systems are incorporated into Act 399. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems are required to test for total coliform and *E.coli*. Total coliform bacteria often originate from the same sources as many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system indicates a minimal likelihood that pathogens are present. *E.Coli* is itself a pathogen and its detection is considered direct evidence of a health risk.

The BWAs which occurred in the City were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City collaboratively in consultation with the DEQ.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to rescind a BWA under these circumstances would be expected to take 3 to 4 days.

Upon receiving information indicating total coliform and *E. Coli* bacteria had been detected, DEQ advised the City to issue a BWA from August 15 through 20, 2014, for the affected portion of the City. Another BWA was issued from September 5 through 9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City. The advisory covered an area approximately 6 square miles or less than 20 percent of the water department's service area of just over 34 square miles.

No total coliform or *E. Coli* bacteria detections have been reported in the City since September 2014.

V. TOTAL TRIHALOMETHANES (TTHM) VIOLATIONS

1. What caused the TTHM violations experienced by the City beginning in late summer 2014?

Disinfectants are an essential element of drinking water treatment because of the barrier they provide against waterborne disease-causing microorganisms. However, disinfection byproducts (DBPs) form when disinfectants used to treat drinking water react with naturally occurring materials in the water (e.g., decomposing plant material).

TTHM (chloroform, bromoform, bromodichloromethane, and dibromochloromethane) and halogenated acetic acids (HAA5 – monochloro-, dichloro-, trichloro-, monobromo-, dibromo-) are widely occurring classes of DBPs. The amount of TTHM and HAA5 in driking water from one water system can change from day to day, depending on the season, water temperature, amount of chlorine added, the amount of plant material in the water, and a variety of other factors. All community water systems that chemically disinfect or purchase water that has been chemically disinfected are required to monitor for DBPs.

The Flint River has higher levels of organic material than water in the Great Lakes and as a result the water produced by the City developed higher disinfection byproducts than the water provided by DWSD. However, because the WTP was previously operating intermittently as an emergency backup supply with water being wasted rather than entering the distribution system, it was not possible to predict disinfection byproduct formation until the City began relying on it continuously.

2. How were the violations detected? What was the DEQ's response?

In preparing to rely on the Flint River, the City installed an ozone treatment system to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 maximum contaminant levels (MCLs) are calculated based on a running annual average at specific distribution system locations, the actual violation of the federal SDWA standard did not occur until the fall of 2014. However, it was apparent in the summer of 2014 that the standard would eventually be exceeded; the DEQ asked the City to proactively implement measures to address the problem before the violation required them to do so. In addition to operational changes to minimize residence time in the distribution system, the City added granular activated carbon to their filters after receiving a construction permit from the DEQ on July 14, 2015. Levels of TTHMs and HAA5s were reduced and the City returned to compliance with the running annual average (MCL) on September 1, 2015.

VI. THE TASTE, ODOR, AND ~~SMELL~~ COMPLAINTS RECEIVED BY FLINT

1. What caused the taste and odor complaints received by the City from residents?

Taste and odor issues are very personalized. ~~Some water systems receive complaints because of too much disinfectant.~~ In the City, during the summer after the switch to the Flint River as a water source, taste and odor complaints increased. At the time, increases in odor and changes in taste appear to occur because of changes in hydraulic conditions within the distribution system. Water leaving the WTP did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing, and changes in flow characteristics are all known causes of disturbances with the distribution system that can cause an increase in taste and odor. Aesthetic taste and odor, while a concern, alone are not a threat to public health.

2. What was the DEQ's response?

The DEQ consulted with the City regarding these complaints. The City indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but City personnel informed the DEQ that they were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHMs, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) often causes temporary problems as described. Based on information from City personnel, it appeared that the complaints were related to such operational activities occurring in the distribution system.

VII. ~~THE~~ LEAD ISSUES IN THE FLINT DRINKING WATER

1. What causes lead in drinking water?

Lead is rarely found in source water. Lead enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead fixtures, and solder. Older homes built prior to World War II, are more likely to contain lead pipes. The most common problem with newer construction is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. Are there any safe levels of lead?

The federal SDWA requires the USEPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called MCLG. The MCLG for lead is zero. The USEPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

3. What is the Lead and Copper Rule?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, the USEPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 parts per million (ppm) in more than 10 percent of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the AL for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control. the water system

4. What are the lead action levels (ALs)? maximum contaminant level

For most contaminants, the USEPA sets an enforceable regulation called an MCL based on the MCL Goal (MCLG). MCLs are set as close to the MCLGs as possible, considering cost, benefits and the ability of public water systems to detect and remove contaminants at the WTP using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, the USEPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to control a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper Rule) requires water systems that produce drinking water to control the corrosivity of the water. The regulation also requires systems to collect customer tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10 percent of a system's tap water samples exceed the lead AL of 15 parts per billion (ppb), then water systems are required to take additional actions including:

•Taking further steps to optimize their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control). Fuel?

•Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

•Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

5. Did DWSD have a corrosion control plan?

After the LCR passed in 1991, DWSD and all of their consecutive customer systems conducted two rounds of monitoring for lead and copper. Copper levels were well below AL limits; but lead levels exceeded the AL of 15 ppb in Detroit and many of their customer communities. As a result, DWSD installed corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an orthophosphate.

6. Did the DEQ require the City to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. There are two ways under the LCR to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment if it is needed. The DEQ requested that the City perform two 6-month rounds of monitoring to demonstrate if the City was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the City would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the City had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the City had not been the supplier of water before, the DEQ did not require the City to "maintain" corrosion control for which it was not responsible. It could not "maintain" operations undertaken elsewhere by a different entity for a different source of water. The DEQ's instructions to the City were consistent with its past practices and its belief that the City should have been afforded the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full-scale monitoring under the applicable rules. For these reasons, two 6-month rounds of monitoring, as required by the LCR were the required means to determine whether or not optimal corrosion control was being achieved.

7. How does the DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the procedure below is followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). ~~Multiples of 10 require~~ no averaging or interpolation. The 90th percentile must be interpolated if the number of samples is not a multiple of 10.

8. What was the result of the first round of monitoring conducted by the City?

The first 6-month round of lead and copper monitoring conducted by the City ended on December 31, 2014. One hundred samples were submitted and the 90th percentile lead level was calculated to be 6 ppb.

A 90th percentile lead result of 6 ppb is not unusual and did not approach the AL or cause alarm. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels between 5 ppb and 15 ppb. For example, in 2014, the following communities had lead results as indicated: DWSD (2.3 ppb), Grand Rapids (2.2 ppb), Kalamazoo (13 ppb), Lansing Board of Water and Light (7.8 ppb), and Saginaw (8 ppb).

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the City ended on June 30, 2015. Sixty-nine samples that complied with the site selection criteria submitted and the 90th percentile lead level was calculated to be 11 ppb. The conclusion from these results was that the City, while in compliance with the AL, exceeded the level required to be deemed as having optimized corrosion control.

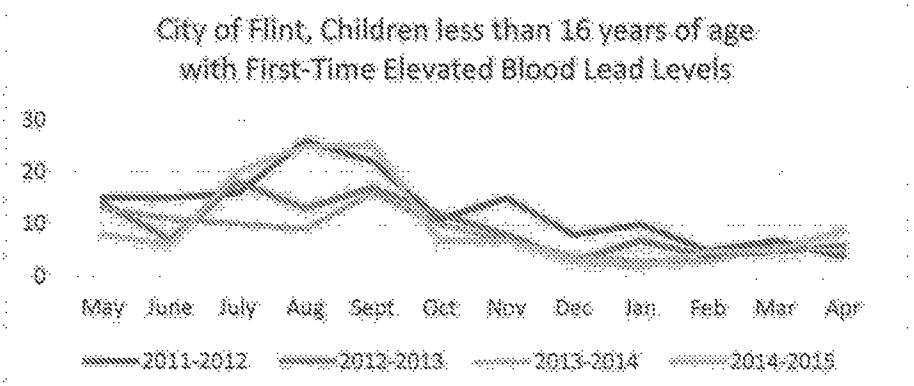
10. Why was the City required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of Act 399.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

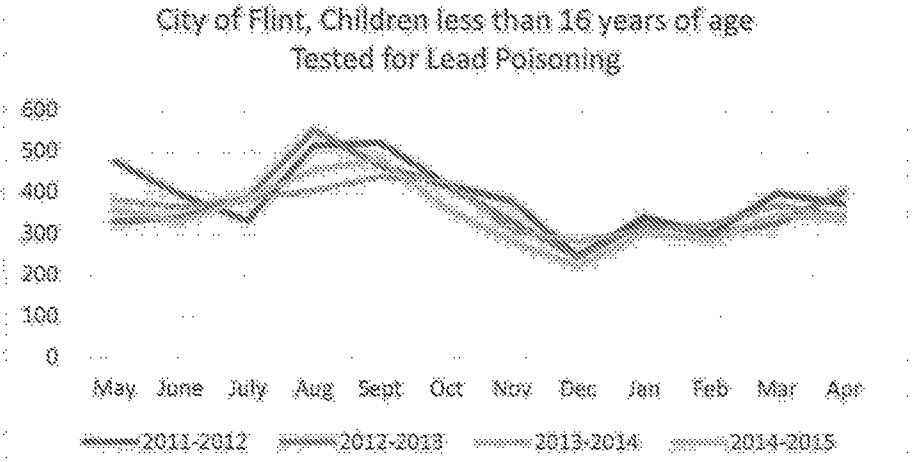
The number of samples the City was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census, which listed the City's population as more 100,000 residents. In March of 2015, the City provided updated information that indicated the City's population had decreased to less than 100,000. Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

11. What actions did the DEQ order the City to undertake after the second round of monitoring?



While the City's LCR compliance monitoring continued to meet AL requirements, the City exceeded the level required to be deemed as having optimized corrosion control. Following receipt of the City's compliance monitoring results, the DEQ required the City to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the City has 6 months to let the DEQ know whether it intends to conduct a study, then 18 months to perform the study and make their recommendation, and 24 months to complete installation of the selected corrosion control. The DEQ requested the City to accelerate this schedule. The City submitted plans and specifications to install corrosion control treatment and a construction permit was issued by the DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November 2015.



12. What had Department of Health and Human Services (DHHS) advised the DEQ regarding blood lead levels prior to the DEQ ordering the City to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year-to-year (chart on the right).

- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).

- However, that pattern was not terribly different from what we saw in the previous three years; especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).

- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspected that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

This e-mail from DHHS in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City had not exceeded an AL for lead provided the basis for the DEQ to maintain that the water in the City continued to be in compliance with the federal SDWA and was safe for consumption.

13. When did the DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015, by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by the USEPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August. In early September 2015, information was reported in news articles that pediatricians in the City had data suggesting an increase in children's blood lead levels in two zip codes in the Flint area.

By this time, the City had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment as documented in correspondence dated August 17, 2015.

VIII. QUESTIONS RAISED REGARDING THE DEQ'S ACTIONS

1. What was the DEQ's response to the USEPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by the City under the LCR?

The DEQ indicated that the City was in compliance with the LCR. 90th percentile levels were below the AL of 15 ppb and not unusual when compared to other large Michigan cities. The City was already conducting the second round of monitoring which would provide for a determination of whether additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the LCR that lead results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile AL in the LCR.

2. Did the DEQ attempt to mislead the USEPA in a February 27, 2015, e-mail responding to the USEPA's inquiry regarding Optimal Corrosion Control Treatment (OCCT)?

No. There is an e-mail from Steve Busch indicating that the City was practicing a corrosion control program. What was meant was that the City was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". The DEQ subsequently clarified its position in follow-up telephone conversations with the USEPA.

3. Has the USEPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by the DEQ?

Yes. On November 3, 2015, the USEPA issued a Memorandum to all 50 states regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of OCCT, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The USEPA states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's OCCT procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take or apply in the future. By admitting that the LCR is subject to differing interpretations, the DEQ believes its interpretation and application of the LCR has been validated.

4. Did the DEQ reject any of the samples submitted by the City?

Yes, samples at two locations were excluded from the compliance calculation in conformance with rules issued by the USEPA.

According to the LCR, compliance samples must be a first draw, 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted high-risk sampling sites, called Tier 1 sampling sites. For a municipality such as the City, the Tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

As long as a community has Tier 1 sites that contain lead services, they are required to collect at least 50 percent of their compliance samples from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc.

One of the samples submitted by the City was excluded from the 90th percentile compliance calculation in the latest monitoring period because it was taken from a tap at a non-residential site. The other sample result that was removed was collected from a single family home that has a whole house treatment system. Both of these sites are, therefore, excluded from the compliance consideration based upon federal rules. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point-of-use or point-of-entry treatment can only be used if the community has insufficient Tier 1 sites available.

5. **Did the DEQ review the information submitted by the City to ensure all samples were from Tier 1 sites?**

Yes. The DEQ examined the information submitted and certified by the City that their LCR sampling pool consisted entirely of lead service lines from single-family homes, which met the requirements of this rule to maximize sampling of high-risk targeted sites.

During the initial implementation of the LCR approximately 25 years ago, water supplies were required to complete a materials evaluation of their distribution system to identify a pool of targeted, high-risk sampling sites. These sites were to be categorized into one of three tiers (I, II or III) based on risk. The DEQ created an LCR reporting template for water systems to identify each compliance sampling site by Tier, and if they are in the highest Tier (1), to indicate why these sites qualify by having a lead service line, or because they either have copper piping installed with high lead content solder or they have lead plumbing in the home.

If a water system has sufficient Tier 1 sites, they are required to sample them before using any lower Tier sites. Furthermore, if they have sufficient sampling sites with lead service lines, they are required to use them to make up at least 50 percent of their sampling pool each monitoring period. Water supplies are also required to use the same sampling sites each time or explain on their LCR reporting form why they were unable to do so. Finally, we require the water system to certify all of the information they provide on the LCR reporting form is factual.

The DEQ must rely upon the public water system to identify appropriate sampling sites for LCR monitoring. The DEQ public water supply program has no control or authority over service lines or domestic plumbing. As a result, we have no records on construction standards or materials used by customers for these components. If these records exist, they are kept locally where they are reviewed and approved by local agencies such as building departments or plumbing inspectors.

In 2015, City employees again certified that the information submitted on their LCR monitoring reports for the two 6-month rounds of monitoring conducted after they began treating the Flint River were accurate, and DEQ staff review of that information indicated it was in compliance with the monitoring requirements. It was not until October 2015 when the DEQ heard City employees revealing to the media that they did not know for certain if their compliance monitoring was collected from homes with lead service lines. As a result, the DEQ began to investigate their monitoring sites. As the City began to transfer their

customer information to electronic records, the DEQ determined from the information available that a significant number of these sites that had been listed as having lead service lines either did not have them or the information was unavailable. On November 9, 2015, the DEQ notified the City in writing that it would be necessary to conduct a complete assessment of their sampling pool and report back their findings within a month. The DEQ is now awaiting the City's report.

6. Did the DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The City replaced the lead service line May 6, 2015. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem, and subsequent sampling taken at this address showed that replacement of the service line did mitigate the problem. There was, therefore, also no reason to believe that this was indicative of a system-wide problem.

7. Do the DEQ's sampling instructions comply with the LCR?

We continue to disagree with the USEPA on sampling protocols. We have attempted to ensure compliance with the USEPA's guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, we had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was the USEPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in compliance calculations. Subsequently, the USEPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, we devised our current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

We continue to believe it is appropriate to flush these taps the day before sample collection to simulate and/or ensure typical household use before the tap is allowed to sit overnight to achieve the expected stagnation time (the regulation recommends a minimum 6 hours stagnation prior to collecting the first draw sample). The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. Until the USEPA changes this rule, we are satisfied with our sampling protocol.

8. Does the DEQ require the use of small-neck bottles to obtain samples?

No. The DEQ does not mandate the use of small-neck bottles; it is the sampling method that is specified in both the federal SDWA and Act 399. Each certified drinking water laboratory provides bottles to their customers upon request for any particular analysis. The bottles provided by the DEQ Drinking Water Laboratory for a lead and copper corrosion control sample do happen to have a small cap opening.

9. Why did the DEQ admit mistakes and apologize?

The mounting Freedom of Information Act Requests brought to the director's attention, information from within the DEQ that was not previously known to Director Dan Wyant– specifically, that the USEPA field staff had raised the question of corrosion control in the spring of 2015 and had been critical of the DEQ's protocol and testing process. It seemed clear that the USEPA field staff had opined that DEQ staff had employed the incorrect protocol. In the face of that new information, Direct Wyant felt compelled to acknowledge that an error may have been made as part of moving the conversation and the situation forward.

The subsequent acknowledgement by the USEPA's regional and headquarters leadership that the LCR speaks ambiguously on the issue of continued corrosion control, and that the DEQ did not employ a protocol that was 'wrong,' was of considerable consolation to the DEQ staff but only left agency leadership feeling more resolute that the LCR needs to be changed, and the DEQ is interested in being part of that process.

Also, there should not have been any disrespect or discredit for those who raised the lead in water issue in Flint. For a tone that did not recognize the seriousness or the issue, Director Wyant did apologize.

9. To which mistake did the DEQ Department Director refer to regarding DEQ's actions on October 18, 2015?

There is ambiguity about how the federal Lead and Copper Rule applies to the situation in Flint.. Upon immediate analysis, it appeared that the DEQ may not have followed the appropriate protocol specified in the LCR for corrosion control treatment for cities with populations of greater than 50,000. Upon further review of the LCR, on November 3, 2015, the US EPA issued updated guidance on the appropriate optimal corrosion control treatment for large water systems switching from purchased treated water to a new source, acknowledging that there were "differing possible interpretations" of the LCR for this circumstance. The DEQ Director respects those voices that raised the issue of lead exposure in Flint and apologizes to those who may have believed that the DEQ's tone discredited their concerns. The DEQ will actively pursue clarifying amendments to the LCR to prevent such situations in other cities.

V. E.Coli and Total Coliform bacteria violations

1. What caused the E.Coli and Total Coliform bacteria violations experienced by Flint in August-September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWA's) in the City of Flint during August and September 2014. While the Flint River has higher levels of natural organic matter than typically found in the Great Lakes, Flint's water treatment plant (WTP) performed well above requirements for removal of organic carbon. In addition, the coliform detections were confined to less than 20% of the water system. If treatment had been compromised, detections would been expected throughout the city rather than in such a limited geographic area.

The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of unlined, cast iron piping. This cast iron pipe is subject to internal corrosion, called tuberculation, which thins and weakens the pipe walls in some areas and causes a buildup of sediment and debris on the pipe walls in other areas. Tuberculation can lead to water quality issues as well as reduced flows and pressures. Tuberculation also encourages the development of biofilms, or layers of bacteria that attach to the rough surfaces of interior pipe walls. Biofilm growth is common in areas where little or no disinfectant residual is maintained, and together with tuberculation, may clog water lines to the point of insufficient water pressure.

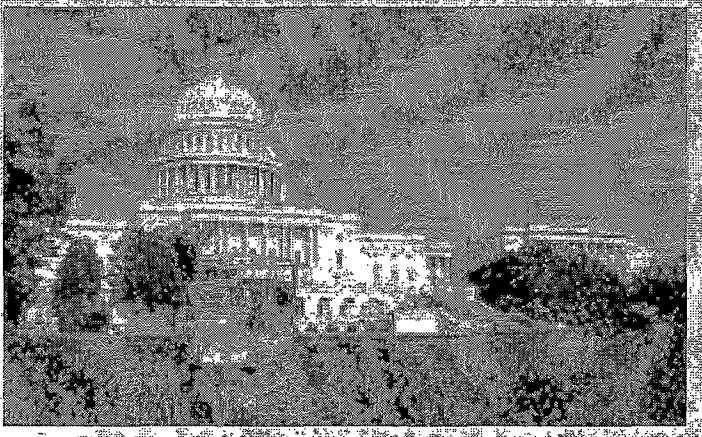
The City has also experienced decades of a declining customer base and water use, with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time (stagnation) within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and loss of disinfectant residual. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination. These hydraulic disturbances were also believed to be the source of the aesthetic water quality complaints both the city and DEQ were receiving.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30%, saw even greater losses since February of that year due to an increase in cold weather related water main breaks and leaks. The City has also been lacking a formal maintenance program for its more than 7,250 valves, which are critical in limiting the areas impacted during water main repairs. As an example, two valves on the transmission line used to supply the area of the 2014 BWAs were found to be closed during the City's investigation of possible sources, causing much longer residence times, reduced disinfectant residuals, and reduced pressures – all potential avenues for contamination to enter a distribution system.

The BWA's also occurred during the warmest, and for 2014, relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the disinfectant residuals more quickly. As already explained, longer residence times, biofilms, and tuberculation contribute to disinfectant residual degradation. Warm, wet weather conditions also allow water contaminated with bacteria to accumulate or pond around piping that leaks or breaks.

During the summer of 2014, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were many broken or closed valves in the distribution system. As the city began correcting this problem they did detect the presence of coliform organisms in the distribution system in the testing conducting as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and

localized pressure losses. ~~For this reason, precautionary BWAs are often issued when communities lose pressure in all or a portion of their system without first sampling to determine if contamination has entered the system.~~



Understanding the Safe Drinking Water Act

SAFE DRINKING WATER ACT • 1974-2004 • PROTECT OUR HEALTH FROM SOURCE TO TAP

The Safe Drinking Water Act (SDWA) was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply.

The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources—rivers, lakes, reservoirs, springs, and ground water wells. (SDWA does not regulate private wells which serve fewer than 25 individuals.)

SDWA authorizes the United States Environmental Protection Agency (US EPA) to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water. US EPA, states, and water systems then work together to make sure that these standards are met.

Millions of Americans receive high quality drinking water every day from their public water systems, (which may be publicly or privately owned). Nonetheless, drinking water safety cannot be taken for granted.

There are a number of threats to drinking water: improperly disposed of chemicals; animal wastes; pesticides; human threats; wastes injected underground; and naturally-occurring substances can all contaminate drinking water.

Likewise, drinking water that is not properly treated or disinfected, or which travels through an improperly maintained distribution system, may also pose a health risk.

Originally, SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

All public water systems must have at least 15 service connections or serve at least 25 people per day for 60 days of the year.

Drinking water standards apply to water systems differently based on their type and size.

Community Water System (there are approximately 54,000) - A public water system that serves the same people year-round. Most residences including homes, apartments, and condominiums in cities, small towns, and mobile home parks are served by Community Water Systems.

Non-Community Water System - A public water system that serves the public but does not serve the same people year-round. There are two types of non-community systems:

Non-Transient Non-Community Water System (there are approximately 20,000) - A noncommunity water system that serves the same people more than six months per year, but not year-round, for example, a school with its own water supply is considered a non-transient system.

Transient non-community water system (there are approximately 89,000) - A non-community water system that serves the public but not the same individuals for more than six months, for example, a rest area or campground may be considered a transient water system.

1996 SDWA Amendment Highlights:

Consumer Confidence Reports All community water systems must prepare and distribute annual reports about the water they provide, including information on detected contaminants, possible health effects, and the water's source.

Cost-Benefit Analysis US EPA must conduct a thorough cost-benefit analysis for every new standard to determine whether the benefits of a drinking water standard justify the costs.

Drinking Water State Revolving Fund States can use this fund to help water systems make infrastructure or management improvements or to help systems assess and protect their source water.

Microbial Contaminants and Disinfection Byproducts US EPA is required to strengthen protection for microbial contaminants, including Cryptosporidium, while strengthening control over the byproducts of chemical disinfection. The Stage 1 Disinfectants and Disinfection Byproducts Rule and the Interim Enhanced Surface Water Treatment Rule together address these risks.

Operator Certification Water system operators must be certified to ensure that systems are operated safely. US EPA issued guidelines in February 1999 specifying minimum standards for the certification and recertification of the operators of community and non-transient, noncommunity water systems. These guidelines apply to state Operator Certification Programs. All states are currently implementing EPA-approved operator certification programs.

Public Information & Consultation SDWA emphasizes that consumers have a right to know what is in their drinking water, where it comes from, how it is treated, and how to help protect it. US EPA distributes public information materials (through its Safe Drinking Water Hotline, Safewater web site, and Water Resource Center) and holds public meetings, working with states, tribes, water systems, and environmental and civic groups to encourage public involvement.

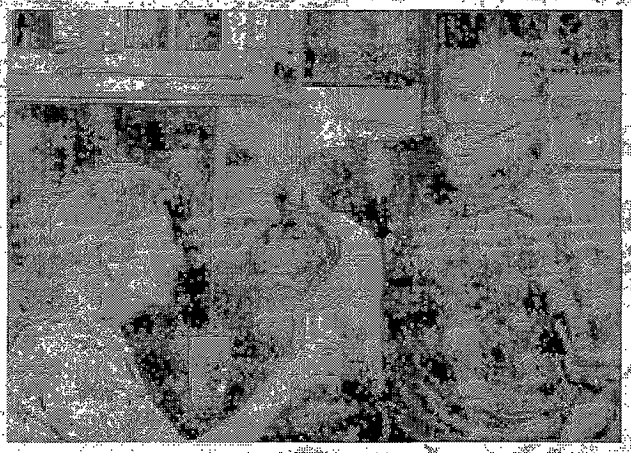
Small Water Systems Small water systems are given special consideration and resources under SDWA, to make sure they have the managerial, financial, and technical ability to comply with drinking water standards.

Source Water Assessment Programs Every state must conduct an assessment of its sources of drinking water (rivers, lakes, reservoirs, springs, and ground water wells) to identify significant potential sources of contamination and to determine how susceptible the sources are to these threats.

Roles and Responsibilities:

SDWA applies to every public water system in the United States. There are currently more than 170,000 public water systems providing water to almost all Americans at some time in their lives. The responsibility for making sure these public water systems provide safe drinking water is divided among US EPA, states, tribes, water systems, and the public. SDWA provides a framework in which these parties work together to protect this valuable resource.

US EPA sets national standards for drinking water based on sound science to protect against health risks, considering available technology and costs. These National Primary Drinking Water Regulations set enforceable maximum contaminant levels for particular contaminants in drinking water or required ways to treat water to remove contaminants. Each standard also includes requirements for water systems to test for contaminants in the water to make sure standards are achieved. In addition to setting these standards, US EPA provides guidance, assistance, and public information about drinking water, collects drinking water data, and oversees state drinking water programs.



The most direct oversight of water systems is conducted by state drinking water programs. States can apply to US EPA for "primacy," the authority to implement SDWA within their jurisdictions, if they can show that they will adopt standards at least as stringent as US EPA's and make sure water systems meet these standards. All states and territories, except Wyoming and the District of Columbia, have received primacy. While no Indian tribe has yet applied for and received primacy, four tribes currently receive "treatment as a state" status, and are eligible for

primacy. States, or US EPA acting as a primacy agent, make sure water systems test for contaminants, review plans for water system improvements, conduct on-site inspections and sanitary surveys, provide training and technical assistance, and take action against water systems not meeting standards.

To ensure that drinking water is safe, SDWA sets up multiple barriers against pollution. These barriers include: source water protection, treatment, distribution system integrity, and public information. Public water systems are responsible for ensuring that contaminants in tap water do not exceed the standards. Water systems treat the water, and must test their water frequently for specified contaminants and report the results to states. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers. Many water suppliers now are also required to prepare annual reports for their customers. The public is responsible for helping local water suppliers to set priorities, make decisions on funding and system improvements, and establish programs to protect drinking water sources. Water systems across the nation rely on citizen advisory committees, rate boards, volunteers, and civic leaders to actively protect this resource in every community in America.

Protection & Prevention:

Essential components of safe drinking water include protection and prevention. States and water suppliers must conduct assessments of water sources to see where they may be vulnerable to contamination. Water systems may also voluntarily adopt programs to protect their watershed or wellhead, and states can use legal authorities from other laws to prevent pollution. SDWA mandates that states have programs to certify water system operators and make sure that new water systems have the technical, financial, and managerial capacity to provide safe drinking water. SDWA also sets a framework for the Underground Injection Control (UIC) program to control the injection of wastes into ground water. US EPA and states implement the UIC program, which sets standards for safe waste injection practices and bans certain types of injection altogether. All of these programs help prevent the contamination of drinking water.

US EPA sets primary drinking water standards through a three-step process:

First, US EPA identifies contaminants that may adversely affect public health and occur in drinking water with a frequency and at levels that pose a threat to public health. US EPA identifies these contaminants for further study, and determines contaminants to potentially regulate. Second, US EPA determines a maximum contaminant level goal for contaminants it decides to regulate. This goal is the level of a contaminant in drinking water below which there's no known or expected risk to health. These goals allow for a margin of safety. Third, US EPA specifies a maximum contaminant level, the maximum permissible level of a contaminant in drinking water which is delivered to any user of a public water system. These levels are enforceable standards, and are set as close to the goals as feasible. SDWA defines feasible as the level that may be achieved with the use of the best technology, treatment techniques, and other means which US EPA finds (after examination for efficiency under field conditions) are available, taking cost into consideration. When it is not economically or technically feasible to set a maximum level, or when there is no reliable or economic method to detect contaminants in the water, US EPA instead sets a required Treatment Technique which specifies a way to treat the water to remove contaminants.

Setting National Drinking Water Standards:

US EPA sets national standards for tap water which help ensure consistent quality in our nation's water supply. US EPA prioritizes contaminants for potential regulation based on risk and how often they occur in water supplies. (To aid in this effort, certain water systems monitor for the presence of contaminants for which no national standards currently exist and collect information on their occurrence). US EPA sets a health goal based on risk (including risks to the most sensitive people, e.g., infants, children, pregnant women, the elderly, and the immuno-compromised). US EPA then sets a legal limit for the contaminant in drinking water or a required treatment technique—this limit or treatment technique is set to be as close to the health goal as

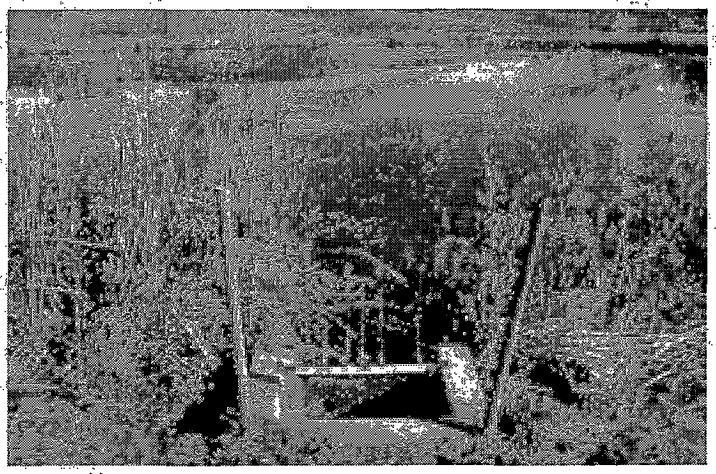
feasible. US EPA also performs a cost-benefit analysis and obtains input from interested parties when setting standards. US EPA is currently evaluating the risks from several specific health concerns, including: microbial contaminants (e.g., *Cryptosporidium*); the byproducts of drinking water disinfection; radon; arsenic; and water systems that don't currently disinfect their water but get it from a potentially vulnerable ground water source.

Funding and Assistance:

US EPA provides grants to implement state drinking water programs, and to help each state set up a special fund to assist public water systems in financing the costs of improvements (called the drinking water state revolving fund). Small water systems are given special consideration, since small systems may have a more difficult time paying for system improvements due to their smaller customer base. Accordingly, US EPA and states provide them with extra assistance (including training and funding) as well as allowing, on a caseby- case basis, alternate water treatments that are less expensive, but still protective of public health.

Compliance and Enforcement:

National drinking water standards are legally enforceable, which means that both US EPA and states can take enforcement actions against water systems not meeting safety standards. US EPA and states may issue administrative orders, take legal actions, or fine utilities. US EPA and states also work to increase water systems' understanding of, and compliance with, standards.



Public Information:

SDWA recognizes that since everyone drinks water, everyone has the right to know what's in it and where it comes from. All water suppliers must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports on the source and quality of their tap water. States and US EPA must prepare annual summary reports of water system compliance with drinking water safety standards and make these reports available to the public. The public must have a chance to be involved in developing source water assessment programs, state plans to use drinking water state revolving loan funds, state capacity development plans, and state operator certification programs.

For More Information:

To learn more about the Safe Drinking Water Act or drinking water in general, call the Safe Drinking Water Hotline at 1-800-426-4791, or visit US EPA's Office of Ground Water and Drinking Water web site: *www.epa.gov/safewater*.

City of Flint Drinking Water

Outline prepared by the

Michigan Department of Environmental Quality for the

Flint Water Task Force

I. Introduction

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act with respect to events in the City of Flint.

II. Background

1. How has Flint historically obtained its drinking water?

The water system in Flint, Michigan, was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally owned corporation which supplied drinking water to the City until 1967, when the City switched and become a customer of the Detroit Water and Sewerage Department (DWSD) system. After the switch to DWSD, the city of Flint operated their water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD was out of service for any reason.

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Michigan's Safe Drinking Water Act (1976 PA 399) and to keep mechanical equipment in good working order, such as valves, rubber seals, etc. Each time the plant was test run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules must be complied with in order to ensure safe drinking water is provided to Flint residents?

The federal Safe Drinking Water Act (SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the SDWA, EPA sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (SDWA does not regulate private wells which serve fewer than 25 individuals.)

The federal SDWA authorizes the United States Environmental Protection Agency (US EPA) to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water. US EPA, states, and water systems then work together to make sure that these standards are met.

Originally, the SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to US EPA for "primacy," the authority to implement SDWA within their jurisdictions, if they can show that they will adopt standards at least as stringent as US EPA's and make sure water systems meet these standards. Michigan adopted the Safe Drinking Water Act in 1976 and maintained primacy for the program since 1978? – not sure we let set of rules we called that yet only say "primacy" time

3. **What is EPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the Safe Drinking Water Act (SDWA), the U.S. Environmental Protection Agency (US EPA) is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards.

Michigan's drinking water program is reviewed annually by U.S. EPA.

4. **What is DEQ role's as a regulatory agency in implementing the SDWA?**

SDWA also allows states to accept oversight of the drinking water program under an agreement with US EPA giving states primary enforcement (or primacy) responsibilities. In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes. Michigan has had a regulatory program providing oversight of PWS since 1913, I – could mention the Act?

The DEQ has primary enforcement authority in Michigan for the ~~Safe Drinking Water Act~~ under the legislative authority of the Michigan Safe Drinking Water Act (Act 399). As such, the ~~division~~ has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies.

The State of Michigan DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: visiting water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; providing financial assistance for system improvements~~; and conducting training sessions~~.

5. What is Flint's role in implementing the SDWA?

These federal and state programs are separate from the activities performed by water systems. State and federal programs develop regulations and perform oversight and compliance activities, but do not actually treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers.

To ensure that drinking water is safe, SDWA sets up multiple barriers against pollution. These barriers include: source water protection, treatment, distribution system integrity, and public information. As a public water system, the city of Flint is responsible for ensuring that contaminants in tap water do not exceed the standards. The City treats the water, and must test their water frequently for specified contaminants and report the results to the State. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The SDWA recognizes that since everyone drinks water, everyone has the right to know what's in it and where it comes from. The City of Flint, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports on the source and quality of their tap water.

The city of Flint submits samples of their water for laboratory testing (monitoring) to verify that the water they provide to its residents meets all federal and state standards. How often and where samples are taken varies from system to system and contaminant to contaminant. The State provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the city of Flint is required to maintain on staff, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the city's water system.

III. The Flint River – it is a safe source of drinking water?

In Michigan, we are blessed with high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, most ~~with intakes~~ in the Great Lakes. A handful of public water supplies in Michigan do treat water from inland ~~sources such as~~ rivers or groundwater under the influence of surface water. ~~While~~ River sources present a greater challenge for treatment because of how rapidly ~~the~~ water quality can change ~~over time~~ compared to Great Lakes sources.

[Our impression is that the average citizen is under the impression that the river water is corrosive and contains lead – we can address no lead, chloride, and lime issues. Address treatment issues to show that water leaving the plant meet all SDWA

requirements. Ph was same as DWSD. Also sets up point that problems arose after water left plant and was disseminated throughout system]

IV. E. Coli and Total Coliform bacteria violations

1. What caused the E.Coli and Total Coliform bacteria violations experienced by Flint in August-September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWA's) in the City of Flint during August and September 2014. While use of the Flint River increased the amount of natural organic matter in the City's water, the City's water treatment plant (WTP) performed well above treatment requirements for organic carbon removal. In addition, less than 20% of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the City, rather than in such a localized area.

The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30%, saw even greater losses since February due to an increase in cold weather related water main breaks and leaks. The City lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWA were found to be closed during the City's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressures.

The BWA's also occurred during the warmest and for 2014 relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were many broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected and what was DEQ's response?

The Boil Water Advisories (BWAs) which occurred in the City of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City of Flint collaboratively in consultation with the DEQ.

Regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the EPA, have been in effect since 1990, and incorporated into the Michigan Safe Drinking Water Act. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for Total coliform and E.coli. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system minimizes the likelihood that pathogens are present. E.Coli is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for a period of 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

A BWA was issued from August 15–20, 2014, for a portion of the City of Flint due to localized detections of total coliform and E.Coli bacteria. Another BWA was issued from September 5-9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City of Flint. The advisory covered an area approximately 6 square miles. The City of Flint has a total land area just over 34 square miles.

V. TTHM violations

1. What caused the TTHM violations experienced by Flint beginning in late Summer 2014?

TTHMs and HAA5s are the result of organic material in the water reacting with disinfectant used to treat the water. The Flint River has higher levels of organic material than water in the Great Lakes and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products than the water provided by DWSD. However, because the water treatment plant was previously operating intermittently as an emergency backup supply, it was not possible to predict disinfection byproduct formation until the city began relying on it continuously.

2. How were the violations detected and what was DEQ's response?

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't actually violate the safe drinking water act standard until the fall, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, the city was asked to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on September 1, 2015.

IV. The taste, odor, and smell complaints received by Flint

1. What caused the taste and odor complaints received by Flint from residents?

Taste and odor issues are very personalized. Some water systems receive complaints because of too much disinfectant. In Flint, during the summer after the switch to the Flint River as a water source, taste and odor complaints increased. It was believed at the time to be the result of changes in hydraulic conditions within the distribution system. Water leaving the water treatment plant did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing and changes in flow characteristics are all know causes of disturbances with the distribution system that can cause an increase in taste and odor complaints.

2. What was DEQ's response?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

V. The lead issues in the Flint drinking water

1. What causes lead in drinking water?

Lead is rarely found in source water, but enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead pipes, fixtures and solder. The most common problem is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. Lead can leach into water from pipes, solder, fixtures and faucets (brass), and fittings. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What are the lead action levels?

For most contaminants, EPA sets an enforceable regulation called a maximum contaminant level (MCL) based on the MCLG. MCLs are set as close to the MCLGs as possible, considering cost, benefits and the ability of public water systems to detect and remove contaminants using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, EPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to ensure control of a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper rule) requires water systems to control the corrosivity of the water. The regulation also requires systems to collect tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10% of tap water samples exceed the lead action level of 15 parts per billion, then water systems are required to take additional actions including:

•Taking further steps optimize their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control) .

•Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

•Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

3. Are there any safe levels of lead?

The SDWA requires EPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLG) The MCLG for lead is zero. EPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

4. What is the LCR?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, EPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 ppm in more than 10% of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the action level for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

5. Did DWSD have a corrosion control plan?

After the LCR was passed, DWSD conducted two rounds of monitoring at for lead and copper. Copper levels were well below action level limits; but lead levels exceeded the action level of 15 parts per billion in many of their customer communities. As a result, DWSD needed to install corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an ortho-phosphate.

6. Did DEQ require Flint to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. The DEQ believed there were two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to call for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were

initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

7. How does DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the following steps are followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Multiples of 10 require no averaging or interpolation.

8. What was the result of the first round of monitoring conducted by Flint?

The first 6-month round of lead and copper monitoring conducted by the city of Flint ended on December 31, 2014. One hundred samples 100 samples were submitted and the 90th percentile lead level was calculated to be 6 parts per billion.

A 90th percentile lead result of 6 ppb is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the city of Flint ended on June 30, 2015. Sixty nine samples were submitted and the 90th percentile lead level was calculated to be 11 parts per billion. The conclusion from these results was that the city exceeded the level required to be deemed as having optimized corrosion control but did not exceed the action level of 15 parts per billion.

10. What actions did DEQ order Flint to undertake after the second round of monitoring?

While the City's LCR compliance monitoring continued to meet action level requirements, the LCR requires all large systems (those serving over 50,000 people) to optimize corrosion control regardless of their 90th percentile lead concentration. Following receipt of Flint's compliance monitoring results, the DEQ required the city to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the city has 6 months to let the DEQ know whether it intends to conduct a study, 18 months to perform the study, and 24 months to complete installation of corrosion control. The DEQ has requested the city of Flint to accelerate this schedule. The city submitted plans and specifications to install corrosion control treatment and a construction

permit was issued by DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November.

11. What had DHHS advised DEQ regarding blood lead levels prior to DEQ ordering Flint to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.
- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

Insert GRAPHS?

This e-mail in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City of Flint had not exceeded an action level for lead provided the basis for DEQ to maintain that the water in Flint continued to be in compliance with the SDWA and was safe for consumption.

12. When did DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015 by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues…" and similarly notified by U.S. EPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August.

By this time, the City of Flint had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment (n

[Hurley and Edwards all after the fact]

VI. Questions raised regarding DEQ's actions

1. What was DEQ's response to EPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by Flint under the LCR?

DEQ indicated that the city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether ~~or not~~ ~~second round of monitoring which would provide for a determination of whether~~ or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the ~~lead/copper rule~~ that lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

2. Did DEQ attempt to mislead EPA in a February 27, 2015 email responding to EPA's inquiry regarding OCCT?

No. There is an e-mail from Steve Busch indicating that the city was practicing corrosion control. This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

3. Has EPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by DEQ?

On November 3, 2015, U.S. EPA issued a Memorandum regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The memo states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take/apply in the future.

DEQ action not just differing interpretation of rule

4. Did DEQ reject any of the samples submitted by Flint?

Yes, samples at two locations were excluded from the compliance calculation.

Compliance samples must be a first draw, 1 liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc. One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has whole house treatment system (check with Steve). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

5. **Did DEQ review the information submitted by Flint to ensure all samples were from Tier 1 sites?**

6. **Did DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. Subsequent sampling taken at this address showed that replacement of the service line mitigated the problem. There was also no reason to believe that this was indicative of a system-wide problem.

7. **Do DEQ's sampling instructions comply with the LCR?**

8. **Does DEQ require the use of small-neck bottles to obtain samples?** – At the lab

9. **Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?**

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan SDWA.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (check with Steve), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated census that indicated the city's population had decreased to less than 100,000 (check with Steve). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

10. Why did DEQ admit it made a mistake?

Shekter Smith, Liane (DEQ)

From: Prysby, Mike (DEQ)
Sent: Monday, October 13, 2014 3:48 PM
To: Busch, Stephen (DEQ); Shekter Smith, Liane (DEQ); Wurfel, Brad (DEQ); Feuerstein, Heather (DEQ); Willard, Veronica (DEQ); Benzie, Richard (DEQ)
Subject: Media Inquiry

Ron Fonger from the Flint Journal called me today concerning the GM Engine manufacturing plant in Flint and their intent to temporarily terminate water service from Flint and purchase water from Genesee County (via Flint Twp) until Flint is either treating water from KWA or reducing their chloride concentration from their treated water that meets GM's limit for manufacturing. Ron asked if elevated chlorides are a health concern in Flint. I looked up Flint's MOR and noted that the treated water chloride concentration leaving the WTP ranges between 55 and 65 mg/l which, although not optimal (optimal being <20 mg/l), is satisfactory. Concentrations > 250 mg/l become objectionable due to taste & corrosion issues; however, based on the concentration leaving the WTP, we did not have any health-effect concerns. Ron was not able to recall the maximum chloride level acceptable to GM; however, I stressed the importance of not branding Flint's water as "corrosive" from a public health standpoint simply because it does not meet a manufacturing facility's limit for production. Ron also asked if the treatment process adds chloride. I explained that their primary coagulant is ferric chloride and this does add some chloride to the finished water; however, raw water chloride concentration is generally in the mid 40s mg/l; thus, the contribution from ferric chloride is not significant.

7. Do the DEQ's sampling instructions comply with the LCR?

We continue to disagree with the USEPA on sampling protocols. We have attempted to ensure compliance with the USEPA's guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, we had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was the USEPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in compliance calculations. Subsequently, the USEPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, we devised our current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

We continue to believe it is appropriate to flush these taps the day before sample collection to simulate and/or ensure typical household use before the tap is allowed to sit overnight to achieve the expected stagnation time (the regulation recommends a minimum 6 hours stagnation prior to collecting the first draw sample). The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. Until the USEPA changes this rule, we are satisfied with our sampling protocol.

8. Does the DEQ require the use of small-neck bottles to obtain samples?

No. The DEQ does not mandate the use of small-neck bottles. It is the sampling method that is specified in both the federal SDWA and Act 399. Each certified drinking water laboratory provides bottles to their customers upon request for any particular analysis. The bottles provided by the DEQ Drinking Water Laboratory for a lead and copper corrosion control sample do happen to have a small cap opening.

9. Why did the DEQ admit mistakes and apologize?

The mounting Freedom of Information Act Requests brought to the Director's attention, information from within the DEQ that was not previously known to Director Dan Wyant – specifically, that the USEPA field staff had raised the question of corrosion control in the spring of 2015 and had been critical of the DEQ's protocol and testing process. It seemed clear that the USEPA field staff had opined that DEQ staff had employed the incorrect protocol. In the face of that new information, Direct Wyant felt compelled to acknowledge that an error may have been made as part of moving the conversation and the situation forward.

DRAFT

The subsequent acknowledgement by the USEPA's regional and headquarters leadership that the LCR speaks ambiguously on the issue of continued corrosion control, and that the DEQ did not employ a protocol that was 'wrong,' was of considerable consolation to the DEQ staff but only left agency leadership feeling more resolute that the LCR needs to be changed, and the DEQ is interested in being part of that process.

Also, there should not have been any disrespect or discredit for those who raised the lead in water issue in Flint. For a tone that did not recognize the seriousness of the issue, Director Wyant did apologize.

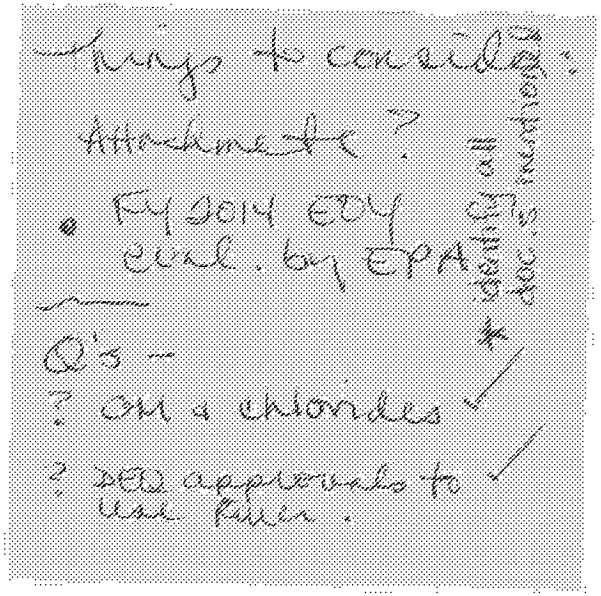
DEQ?

We = DEQ

Add: official clarification

Why is this Q important?

word choice "will continue to use" ... the Michigan ...



Two finger/salute suggest nastiness.

Rework This!

What Mistake did DEQ Dept Director refer to regarding DEQ's actions on date?

- The LCR is "ambiguous" (as evidenced by EPA letter)
- Upon immediate analysis, it appeared that DEQ did not employ the appropriate protocol for a city of >50,000 as ~~[illegible]~~ could be ~~[illegible]~~ read from the LCR.
- On _____ date, the EPA, provided new national guidelines for LCR compliance, including an "ambiguity" in the Rule.
- DEQ Director regrets _____ those raising the lead issue in Flint, and DEQ apologizes to those who may not believe the DEQ's tone might have discredited their concerns

The DEQ will be actively pursuing As to the LCR to prevent such situation in other cities in future.

City of Flint Drinking Water
Outline prepared by the
Michigan Department of Environmental Quality for the
Flint Water Task Force

I. INTRODUCTION

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), with respect to events in the city of Flint (City), Michigan.

II. BACKGROUND

1. How has Flint historically obtained its drinking water?

The water system in the City was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City. In 1967, the City switched and became a customer of the Detroit Water and Sewerage Department (DWSD) system. After the switch to DWSD, the City operated their water treatment plant as a standby, ~~backup emergency~~ plant for purposes of reliability in the event that the single pipeline from DWSD ~~was out of service for any reason~~ had an emergency such as an interruption in service during high demand. In 2009, the water treatment plant was ~~operated~~ used in this emergency capacity in two instances (dates/number of days). Additionally, as a backup emergency plant, the City was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Act 399 and to keep mechanical equipment (such as valves, rubber seals, etc.) in good working order. Each ~~time~~ quarter the plant was test run ~~quarterly~~, samples were taken of raw water ~~quality~~ (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a National Pollutant Discharge Elimination System (NPDES) Permit (confirm with Steve). The test runs were for demonstration purposes ~~only~~, to keep the plant operational and staff familiar with operation in the event it was needed in an emergency. because of contractual obligations with DWSD.

2. What State and Federal laws or rules exist to ensure safe drinking water is provided to City residents?

The federal Safe Drinking Water Act (federal SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the federal SDWA, the United States Environmental Protection Agency (USEPA) sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (The federal SDWA does not regulate private wells which serve fewer than 25 individuals.)

The federal SDWA authorizes the USEPA to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water. USEPA, states, and water systems, then work together to make sure that these standards are met.

Originally, the federal SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to the USEPA for "primacy," the authority to implement the federal SDWA within their jurisdictions if they ~~can show that~~ they will adopt standards at least as stringent as the USEPA's and ~~make sure water systems meet these~~ enforce them standards. Michigan adopted the Safe Drinking Water Act in 1976 through Act 399 and maintained primacy for the program since 1978 that time.

3. **What is the USEPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the federal SDWA, the USEPA is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards, by working with states.

Michigan's drinking water program is reviewed annually by the USEPA.

4. **What is the Michigan Department of Environmental Quality's (DEQ) role as a regulatory agency in implementing the SDWA?**

The federal SDWA ~~also allows~~ permits states to accept oversight of the drinking water program under an agreement with the USEPA giving states primary enforcement (or primacy) responsibilities. In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes. Michigan has had a regulatory authority providing oversight of public water supplies since 1913

The DEQ has primary enforcement authority in Michigan for the federal SDWA under the legislative authority of Act 399. As such, the DEQ, Office of Drinking Water and Municipal Assistance (ODWMA) has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies.

(waterworks and Sewage Systems Act 98 of 1913)

The DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: conducting surveillance visits of water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the examination, certification and regulation of persons operating water supplies; helping

training

systems invest in preventive measures, providing financial assistance for system improvements; ~~and conducting training sessions~~.

5. **What is the City's role in implementing the federal SDWA?**

State and federal programs develop regulations and perform oversight and compliance activities, but do not actually treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers.

To ensure that drinking water is safe, the federal SDWA sets up multiple barriers against pollution. These barriers include: source water protection, treatment, distribution system integrity, and public information. As a public water system, the City is responsible for ensuring that contaminants in tap water do not exceed the standards. The City treats the water, and must test their water frequently for specified contaminants and report the results to the DEQ. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The federal SDWA recognizes that ~~since everyone drinks water, everyone~~ has the right to know what is in it and where it comes from. The City, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports (CCR) on the source and quality of their tap water.

The City submits samples of their water for laboratory testing (monitoring) to verify the water they provide to residents meets all federal and state standards. How often and where samples are taken varies from system to system and contaminant to contaminant. The DEQ provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the City is required to ~~maintain on staff~~ certified water operators that are trained and experienced to operate the treatment and distribution system associated with the City's water system.

III. THE FLINT RIVER – IS IT A SAFE SOURCE OF DRINKING WATER?

In Michigan, we are blessed with high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, most with intakes in the Great Lakes. A handful of public water supplies in Michigan do treat water from inland sources such as rivers or groundwater under the influence of surface water. While river sources present a greater challenge for

[Our impression is that the average citizen is under the impression that the river water is corrosive and contains lead – we can address no lead, chloride, and lime issues. Address treatment issues to show that water leaving the plant meet all SDWA requirements. Ph

was same as DWSD. Also sets up point that problems arose after water left plant and was disseminated throughout system]

IV. *E. COLI* AND TOTAL COLIFORM BACTERIA VIOLATIONS

1. What caused the *E.Coli* and total coliform bacteria violations experienced by the City in August and September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWAs) in the City during August and September 2014. While use of the Flint River increased the amount of natural organic matter in the City's water, the City's water treatment plant (WTP) performed well above treatment requirements for organic carbon removal. In addition, less than 20 percent of the water system was included in the BWA area. If treatment had been compromised, detections would have been widespread throughout the City, rather than in such a localized area.

Instead, the violations seem to have been caused by other factors such as aging infrastructure and unusual weather patterns. The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses and industrial property. Declining water use leads to water spending excess time within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30 percent, saw even greater losses since February 2015 due to an increase in cold weather-related water main breaks and leaks. The City lacks a formal maintenance program for its 7,250+ valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWA were found to be closed during the City's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure.

The BWAs also occurred during the warmest and relatively wet periods of August and September 2014. Warm weather conditions are not only more conducive to bacterial

RB & re-type

growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks. [Why are we talking about the winter of 2014 and then the summer of 2014, this is confusing]

During the summer, the City was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were many broken or closed valves in the City's distribution system. As the City began correcting this problem, they did experience issues of bacteria in the distribution system as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected? What was the DEQ's response?

Regulations regarding monitoring and standards for bacteria in water distribution systems ~~were developed by the USEPA, have been in effect since 1990, and~~ are incorporated into Act 399. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for total coliform and *E.coli*. Total coliform bacteria ~~react to water treatment in a manner similar to many pathogens.~~ Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system indicates a minimal likelihood that pathogens are present. *E.Coli* is itself a pathogen and its detection ~~would be~~ direct evidence of a health risk ~~and Water Service Interruptions~~ is considered.

The BWAs which occurred in the City were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City collaboratively in consultation with the DEQ.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take ~~at least~~ 3 to 4 days.

A BWA was issued from August 15 thru 20, 2014, for a portion of the City due to localized detections of total coliform and *E.Coli* bacteria. Another BWA was issued from September 5 thru 9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City. The advisory covered an area approximately 6 square miles. ~~The City has a total land area just over 34 square miles.~~

V. TOTAL TRIHALOMETHANES (TTHM) VIOLATIONS

1. What caused the TTHM violations experienced by the City beginning in late summer 2014?

TTHMs and halogenated acetic acids (HAAS) are the result of organic material in the water reacting with disinfectant used to treat the water. The Flint River has higher levels of organic material than water in the Great Lakes and as a result the water produced by the City developed higher disinfection byproducts than the water provided by DWSD. However, because the WTP was previously operating intermittently as an emergency backup supply, it was not possible to predict disinfection byproduct formation until the City began relying on it continuously.

2. How were the violations detected? What was the DEQ's response?

In preparing to rely on the Flint River, the City installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAAS maximum contaminant levels (MCLs) are calculated based on a running annual average at specific locations, the City did not actually violate the federal SDWA standard until the fall, ~~but because~~ however it was apparent in the summer of 2014 that the standard would eventually be exceeded, the City was asked to proactively implement measures to address the problem before the violation required them to do so. The City added granular activated carbon to their filters (after receiving a construction permit from the DEQ on date?) and levels of TTHMs and HAASs were reduced. The City returned to compliance with the running annual average (MCL) on September 1, 2015.

VI. THE TASTE, ODOR, AND SMELL COMPLAINTS RECEIVED BY FLINT

1. What caused the taste and odor complaints received by the City from residents?

Taste and odor issues are very personalized. Some water systems receive complaints because of too much disinfectant. In the City, during the summer after the switch to the Flint River as a water source, taste and odor complaints increased. ~~It was believed~~ at the time ~~to be the result of~~ changes in hydraulic conditions within the distribution system. Water leaving the WTP did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing, and changes in flow characteristics are all known causes of disturbances with the distribution system that can cause an increase in taste and odor ~~complaints.~~ Taste and odor ~~complaints,~~ while a concern, are not a threat to public health.

2. What was the DEQ's response?

The DEQ consulted with the City regarding these complaints. The City indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but City personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to

help control TTHMs, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) often causes temporary problems as described. Based on information from City personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

VII. THE LEAD ISSUES IN THE FLINT DRINKING WATER

1. What causes lead in drinking water?

Lead is rarely found in source water, but enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead ~~Pipes,~~ fixtures, and solder. The most common problem is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. ~~Lead can leach into water from pipes, solder, fixtures and faucets (brass), and fittings.~~ [REDUNDANT] The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What are the lead action levels (ALs)?

For most contaminants, the USEPA sets an enforceable regulation called an MCL based on the MCL Goal (MCLG). MCLs are set as close to the MCLGs as possible, considering cost, benefits and the ability of public water systems to detect and remove contaminants at the WTP using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, the USEPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to ensure control of a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper Rule) requires water systems to control the corrosivity of the water. The regulation also requires systems to collect tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10 percent of tap water samples exceed the lead AL of 15 parts per billion (ppb), then water systems are required to take additional actions including:

*Taking further steps to optimize their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control).

*Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

*Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

3. Are there any safe levels of lead?

The federal SDWA requires the USEPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called MCLG. The MCLG for lead is zero. The USEPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

4. What is the Lead and Copper Rule?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, the USEPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 parts per million (ppm) in more than 10 percent of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the AL for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

5. Did DWSD have a corrosion control plan?

After the LCR passed in 1991, DWSD conducted two rounds of monitoring for lead and copper. Copper levels were well below AL limits; but lead levels exceeded the AL of 15 ppb in many of their customer communities. As a result, DWSD ~~needed to~~ installed corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an ortho-phosphate.

6. Did the DEQ require the City to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. The DEQ believed municipalities had two options under the LCR to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to require the City to perform two 6-month rounds of monitoring to demonstrate if the City was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the City would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the City had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that

point. Since the City had not been the supplier of water before, the DEQ did not require the City to "maintain" corrosion control for which it was not responsible. It could not "maintain" something that it was not doing. ~~As we stated previously~~, we believed Flint should have been afforded the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the LCR were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

7. How does the DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the ~~following steps are~~ procedure below is followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Multiples of 10 require no averaging or interpolation.

8. What was the result of the first round of monitoring conducted by the City?

The first 6-month round of lead and copper monitoring conducted by the City ended on December 31, 2014. One hundred samples were submitted and the 90th percentile lead level was calculated to be 6 ppb.

A 90th percentile lead result of 6 ppb is not unusual and did not approach the action level or once alarm. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels ~~above 5 ppb – in this range~~ between 5 ppb and 15 ppb.

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the City ended on June 30, 2015. Sixty-nine samples that complied with the site selection criteria were submitted and the 90th percentile lead level was calculated to be 11 ppb. The conclusion from these results was that the City exceeded the level required to be deemed as having optimized corrosion control ~~but did not exceed the AL of 15 ppb.~~ while in compliance with the action level

Insert Q. 9 from last page here.

10. What actions did the DEQ order the City to undertake after the second round of lead monitoring?

While the City's LCR compliance monitoring continued to meet AL requirements, the ~~LCR requires all large systems (those serving over 50,000 people) to optimize corrosion control regardless of their 90th percentile lead concentration.~~ Following receipt of the City's

exceedance level required to be delayed as having

compliance monitoring results, the DEQ required the City to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the City has 6 months to let the DEQ know whether it intends to conduct a study, 18 months to perform the study, and 24 months to complete installation of corrosion control. The DEQ has requested the City to accelerate this schedule. The City submitted plans and specifications to install corrosion control treatment and a construction permit was issued by the DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November 2015.

11. What had Department of Health and Human Services (DHHS) advised the DEQ regarding blood lead levels prior to the DEQ ordering the City to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

* Lead testing rates remained about the same from year-to-year (chart on the right).

* There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).

* However, that pattern was not terribly different from what we saw in the previous three years; especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).

* We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspected that the summer data spike may be related to this effect.

* If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

Insert GRAPHS?

This e-mail in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City had not exceeded an AL for lead provided the basis for the DEQ to maintain that the water in the City continued to be in compliance with the federal SDWA and was safe for consumption.

12. When did the DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015, by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by the USEPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August 2015.

By this time, the City had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment in

[Hurley and Edwards all after the fact]

VIII. QUESTIONS RAISED REGARDING THE DEQ'S ACTIONS

1. **What was the DEQ's response to the USEPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by the City under the LCR?**

The DEQ indicated that the City was in compliance with the LCR. 90th percentile levels were below the AL and not unusual. The City was already conducting the second round of monitoring which would provide for a determination of whether ~~by-pass~~ additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the LCR that lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile AL in the LCR.

2. **Did the DEQ attempt to mislead the USEPA in a February 27, 2015, e-mail responding to the USEPA's inquiry regarding Optimal Corrosion Control Treatment (OCCT)?**

No. There is an e-mail from Steve Busch indicating that the City was practicing corrosion control. This was a misstatement. What was meant was that the City was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with the USEPA.

3. **Has the USEPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by the DEQ?**

Yes. On November 3, 2015, the USEPA issued a Memorandum to all 50 states regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of OCCT, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The memo states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's OCCT procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take or apply in the future.

DEQ maintains . . .

4. Did the DEQ reject any of the samples submitted by the City?

Yes, samples at two locations were excluded from the compliance calculation.

According to the LCR, compliance samples must be a first draw, 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called Tier 1 sampling sites. For a municipality such as the City, the Tier 1 sampling pool must consist of single family structures that are:

high risk

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

As long as a community has Tier 1 sites that contain lead services, they are required to collect at least 50 percent of their compliance samples from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc.

One of the samples submitted by the City was excluded from the 90th percentile compliance calculation in the latest monitoring period because it was taken from a tap at a non-residential site. The other sample result that was removed was collected from a single family home that has a whole house treatment system (check with Steve). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point-of-use or point-of-entry treatment can only be used if the community has insufficient Tier 1 sites available.

5. Did the DEQ review the information submitted by the City to ensure all samples were from Tier 1 sites?

6. Did the DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The City replaced the lead service line (when). Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem, and subsequent sampling taken at this address showed that replacement of the service line did mitigate the problem. There was, therefore, also no reason to believe that this was indicative of a system-wide problem.

7. **Do the DEQ's sampling instructions comply with the LCR?**

8. **Does the DEQ require the use of small-neck bottles to obtain samples?**

9. **Why was the City required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?**

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of Act 399.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples the City was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (check with Steve), which listed the City's population as more 100,000 residents. In March of 2015, the City provided updated information that indicated the City's population had decreased to less than 100,000 (check with Steve). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

10. **Why did the DEQ admit it made a mistake?**

I. **The Flint River – is it a safe source of drinking water?**

In Michigan, we are fortunate to have high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, the majority of which is withdrawn from the Great Lakes. A handful of public water supplies in Michigan do treat water from inland rivers, lakes or groundwater under the influence of surface water. All surface water sources and groundwater under the influence of surface water requires significant treatment in order to be safe for consumption. Treatment of surface water is referred to under Act 399 as "complete treatment". While all surface water sources must receive this higher level of treatment, river sources present a greater challenge than water withdrawn from one of the Great Lakes. River sources are more challenging to treat because of how rapidly water quality may change compared to Great Lakes Sources. Under most circumstances, rivers are also prone to greater fluctuations in temperature, have higher amounts of organic material, greater turbidity (suspended solids), and more microbiological and viral contamination than Lakes Huron, Erie, Michigan or Superior. It should be noted, that while the water chemistry in the Flint River differs from that in Lake Huron, it can still be treated in accordance with the SDWA and Act 399. Many cities across the country rely on similar sources for drinking water. The waterworks industry has the technology to treat wide ranging source waters to provide potable and palatable drinking water, including direct reuse of wastewater. Regardless of source water quality, all public water systems must comply with the same drinking water standards in the finished water.

Also, it is not the source water that reacts with the homeowners plumbing in the distribution system, but rather the finished water quality that is important. To begin with, neither the Flint River nor the treated water leaving the City of Flint's water treatment plant contains lead. In addition, the treatment process employed by the City of Flint includes lime softening to reduce the hardness in the river water. Lime softening is not a process that would typically be thought to increase corrosivity of water. The City of Flint, however, does practice recarbonation to re-adjust pH at the end of the softening process. pH levels of finished water leaving the City of Flint's water treatment plant averaged 7.7. Water monitoring conducted quarterly at 25 sample sites located throughout the distribution system showed the following:

July – September 2014	average pH = 7.71	range: 7.56 – 7.86
October – December 2014	average pH = 7.88	range: 7.62 – 8.10
January – March 2015	average pH = 7.81	range: 7.60 – 7.99
April – June 2015	average pH = ???	range: ???

These numbers compare to the water delivered by DWSD. NEED TO INSERT HERE.

Background –

Prior to switching from DWSD, the city of Flint operated a water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD failed.

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Act 399 and to keep mechanical equipment in good working order, such as valves, rubber seals, etc. Each time the plant was test run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

Do we want to note that the original decision was to join KWA and begin receiving water in ~3 years from Lake Huron? It wasn't until DWSD issued a termination notice that caused the city to consider relying on the Flint River in the interim because they could not agree on a contract extension with Detroit.

April 2014: Flint terminates service from DWSD and begins using their water treatment plant full time.

What approvals from DEQ were required to do this?

Because Flint had long ago been issued construction permits for raw water pumps to withdraw water from the Flint River, the city was grandfathered under the Water Withdrawal program as were all existing community public water systems. There were no additional DEQ permissions required.

Under Act 399, Michigan's Safe Drinking Water Act, there are no licenses or permit required to operate. Two construction permits were issues prior to the treatment plant changing from an emergency back-up plant to a full time operation. These permits were for small changes such as new chemical feed equipment, changes to the electrical service, etc.

Summer 2014: Flint experiences several (how many?) water main breaks and has 2 localized (describe) boil water events.

Do we mention the unusually harsh winter that led to an increased number of water main breaks throughout Michigan that year?

Is it unusual for a city to issue boil water advisories? Should the state have been concerned at this point?

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were (how many) broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs.

This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

Complaints are being made that there are taste, odor, and color issues since the switch from DWSD; including rashes and hair falling out. Why didn't the state do something?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

Late Summer 2014: Monitoring for TTHM's in the distribution system identifies that the city has elevated levels and will violate the MCL for TTHM's in subsequent monitoring.

How was this handled? Should this have been a sign that it was a mistake to "allow" Flint to switch from DWSD to the Flint River?

Because the water treatment plant was originally upgraded for intermittent, emergency use, it was not possible to predict Disinfection Byproduct formation until the city began relying on it continuously. The Flint River had higher levels of organic material and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products. TTHMs and HAA5s are the result of organic material in the water reacting with the disinfectant. On more than one occasion, DEQ district supervisors and engineers have indicated that continuous use of the Flint River poses an increased microbial risk and an increased risk of disinfection byproducts; will trigger additional regulatory requirements for monitoring; and require significant enhancements at the Flint Water Treatment Plant.

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't actually violate the safe drinking water act standard until the fall, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, the city was asked to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on (date?).

What is the role of DEQ as a regulatory agency implementing the Michigan Safe Drinking Water Act?

What is the role of the City of Flint in water system operation and providing safe drinking water?

Issues around lead/copper:

Why didn't DEQ require a corrosion control plan from the city prior to bringing the water treatment plant on-line in April 2014?

DEQ believed there were two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to call for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

The first round of monitoring conducted July 2014 through December 2014 resulted in a 90th percentile of 6 ppb lead. Why didn't the DEQ require the city take actions at this point?

A 90th percentile lead/copper result of 6 ppb for lead is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

In February, EPA staff inquired about corrosion control and whether the city was providing treatment to control corrosion. What was the DEQ's response?

DEQ indicated that they city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that

lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

An e-mail from Steve Busch indicated that the city was practicing corrosion control. Why was this said?

This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

In April, EPA staff visited Flint and sampled a residence at 212 Browning. High levels of lead were present. Why wasn't this seen as a potential system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. There was also no reason to believe that this matter was anything other than a site specific condition. (may not be so unique in terms of Pb levels)

A draft memo, dated June 24, 2015, from an EPA staff person claimed that DEQ had inappropriately handled the sampling at the city and that corrosion control should have been required before start up. What is DEQ's response to these allegations?

DEQ never received this memo and it is our understanding that EPA never sent us this memo. A copy of the draft document was downloaded from the ACLU website. On June 30th, an e-mail was received from EPA that indicated it was a draft memo that had been shared with the homeowner where sampling occurred and that once management had a chance to review the memo they would provide a final copy to DEQ. A final copy was never received. Also, EPA indicated in this same e-mail that a conference call to discuss the issues raised in the memo was scheduled for July 21st between the agencies.

During the July 21st call, EPA provided a rule citation (for the first time) indicating that ..... DEQ provided their interpretation of the lead/copper rule. EPA indicated that they would consult with their attorneys and seek a clarification regarding the two different interpretations. To date (October 20th), DEQ has not received any feedback from EPA regarding the state's interpretation.

There is on-going criticism that the DEQ provides inappropriate guidance to water supplies regarding pre-flushing of taps prior to lead/copper sampling? Explain DEQ's rationale for doing this.

The lead/copper sampling protocol is designed to standardize sample collection and is not the same protocol that would be used for an exposure assessment. Different sampling is done for different purposes.

Under the lead/copper rule, samples collected must be "first-draw' 1 liter samples collected from kitchen or bathroom taps at EPA designated, high-risk locations after

overnight stagnation. It is recognized that this may or may not be the highest level of lead that could be found at a residence. However, it does provide the water supplier with information about efficacy of their treatment process and an indication of how the water may be reacting with plumbing in the system.

The lead/copper rule is the only rule that requires compliance monitoring to be performed by homeowners. In order to simplify the instructions and ensure consistent sampling protocol and results, DEQ recommends that a sample tap/outlet be run the night before it is going to be sampled so that the sampling location is representative of a tap experiencing typical household use (as required by the lead/copper rule). Historically, there were problems with homeowners sampling from locations that had not been used for days, weeks or even months. The recommended/required stagnation period under the lead/copper rule is 6 to 18 hours. To accomplish this across the board, DEQ policy is to recommend that the tap be used or use be simulated on the night before it is going to be sampled. EPA has incorporated similar sampling protocols into tap sampling programs at schools and day care centers. (do we want to provide a footnote with a citation to the Milwaukee Westlawn CARE Project?)

If there is a lead service line in the house, then a first draw sample under this condition will not contain water that has sat stagnant for some time in that service line. However, flushing the tap the night before will not likely result in capturing a first draw sample that has sat stagnant in that lead service line because only the tap that is going to be sampled is required to be stagnant. If there is a toilet or a dishwasher nearby, they can still be used. And it is impossible to predict whether there is water in that particular line that has spent any time at all resting quietly for any period of time in the service line and only happens to be poised for withdrawal at that particular tap at that particular moment. Only a site specific evaluation of a household plumbing system along with a site specific calculation of the volume of water in the plumbing system and the volume of water in the lead service line would potentially provide for a sample that has rested in the service line assuming that no water has been used in the house during the entire time of "resting". This level of complexity is not a practical approach for a community to employ or for water systems across the country to accomplish when they must rely upon homeowners to collect samples. The lead/copper rule is imperfect. But the instructions provided by DEQ provide for a consistent sampling protocol that is easily followed by homeowners and results in samples collected that meet the legal requirements of the lead/copper rule and the intention of providing water quality information upon which further regulatory decisions should be made. The lead/copper rule is intended to assist water suppliers with evaluating their treatment process and the effects of the water on plumbing systems. It is not a tool to assess individual exposure.

After the July 21st call with EPA where they provided a regulatory citation and their opinion that the DEQ had not followed the required protocol to require treatment, what steps were taken by DEQ to address the situation?

By the time the July 21st call occurred, the city had completed their two 6-month rounds of lead/copper monitoring. This monitoring showed that the city needed to install corrosion control measures. On August 17th, the DEQ wrote the city requiring the city to perform a study and install corrosion control treatment in accordance with the safe drinking water act. We also recommended Flint significantly accelerate this action and not take the time allotted by the regulations for selecting and installing OCCT.

When DEQ met with city residents on August 4th, they were still saying that the water was safe even after the sampling was done and it showed that corrosion control was necessary. Why the contradiction?

At the time of this meeting, all sampling results to date indicated that lead levels were within typical ranges seen in other water systems and below the Action Level established in the rule. It was acknowledged that the results showed that the city of Flint needed to provide optimal corrosion control treatment and that would soon be required. In addition, data provided by our colleagues at the Department of Health and Human Services indicated that there was no significant change in children's blood lead levels within the city. The evaluation showed that blood lead levels were following historical seasonal patterns and there was no indication of a water contributing to an increase. This provided backup confirmation (at that time) that the path followed was correct.

When the V-T researcher raised the alarm on (date) that the sampling required by DEQ was wrong and that levels of lead in the city were much higher than previously thought, why didn't DEQ investigate these claims and follow up on this information?

DEQ was informed in late August that a study was underway in the city and that samples taken appeared to be much higher than those taken under the lead/copper rule. Since we were not provided information regarding protocol used for the study, the DEQ could not adequately comment on the comparison between the two data sets. It was not however, unexpected that a different sampling protocol could yield higher results. Since the required two 6-month rounds of monitoring had already been completed at this point and the city had been notified of the requirement to install treatment, there were no additional actions deemed necessary by the agency at this point. The city had not exceeded the lead action level, they were actively pursuing treatment on an accelerated schedule, and DHHS information regarding blood lead levels in the city indicated that there was NO significant change since the switch.

Why did DEQ change their position in September and agree that lead is a problem in Flint?

As soon as the DHHS Chief Medical Officer determined that there was a correlation between blood lead levels in children in certain zip codes and the switch to the Flint River, DEQ responded. Actions were taken within a week to address the concerns raised.

Why is DEQ admitting it made a mistake?

If EPA's interpretation is correct and the city of Flint was required to maintain corrosion control and should not have been allowed to switch sources without maintaining corrosion control, this wasn't done. All indications are that the protective coating that was in place as a result of treated water received from DWSD has been eroded and that lead leaching has increased during the time that there hasn't been treatment. This was the mistake. However, DEQ staff acted in good faith. They believed that they were implementing the lead/copper rule appropriately with all of its nuances in sampling and limitation on compliance monitoring. The lead/copper rule establishes a mechanism for a new supply (when not previously serving water to the public) to conduct two 6-month rounds of monitoring to determine whether or not the supply can be deemed optimal by definition or whether treatment must be installed. It did not anticipate a system serving

greater than 50,000 residents would disconnect from a regional supply to become its own supply with a new source and different treatment methods. It was these circumstances for which DEQ employees were sincerely applying regulations as they interpreted them to ensure compliance and public health protection.

Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan Safe Drinking Water Act (Act 399, PA 1976, as amended).

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (*check with Steve*), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated census that indicated the city's population had decreased to less than 100,000 (*check with Steve*). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

Why were some sample results submitted by the City of Flint during the latest monitoring period excluded from the 90th percentile compliance calculation?

Compliance samples must be 1 liter in volume and be a first draw, 1 liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

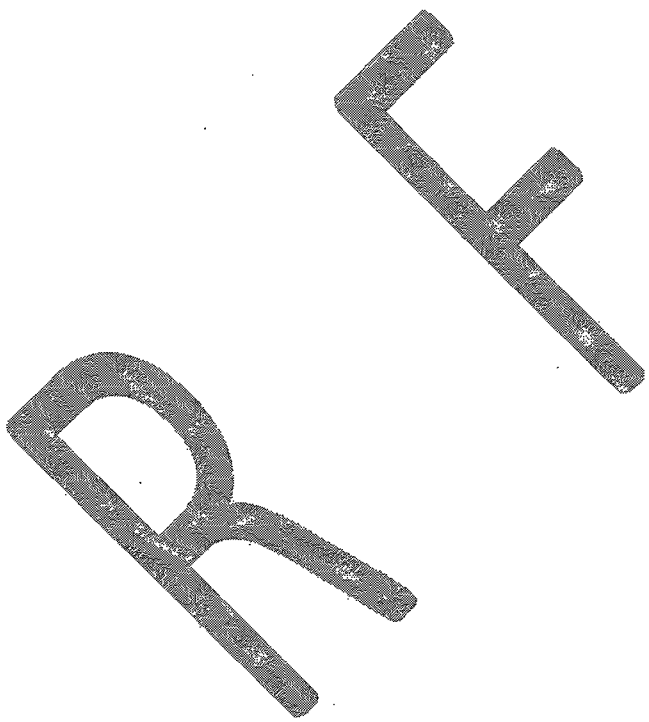
Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters,

etc. One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has point of use treatment (*check with Steve*). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

Although we already addressed the issue of why we did what we did in the first question after the "Issues around lead/copper," the following citation and explanation may be useful if needed to answer additional questions or ones we haven't yet asked:

Rule 325.l1064(f) (2) (D) (iii) says, "A water supply is considered to have optimized corrosion control if it submits results of tap water monitoring conducted under R 325.10710a and source water monitoring conducted under R 325.10710c that demonstrates, for 2 consecutive 6-month monitoring periods, that the difference between the ninetieth percentile tap water lead level computed under subrule (1)(c0) of the rule and the highest source water lead concentration is less than the practical quantification level (PQL) for lead. *(This is the procedure we were applying to Flint as they became a supplier and not just a consecutive system receiving finished water)* In addition, all of the following provisions apply:

(A) A supply whose highest source water lead level is below the method detection limit is considered to have optimized corrosion control under this paragraph if the supply's ninetieth percentile tap water lead level is less than or equal to the PQL for lead (which is 5 ppb) for 2 consecutive 6-month monitoring periods.



(B) A water supply considered to have optimized corrosion control under this paragraph shall continue monitoring for lead and copper at the tap not less frequently than once every 3 calendar years using the reduced number of sites specified in R 325.10710a(3) and collecting the samples at times and locations specified in R325.10710a(4)(d)(iv).

(C) A water supply is considered to have optimized corrosion control under this subdivision shall notify the department, in writing, under R325.10710d(a)(iii) of an upcoming long-term change in treatment or addition of a new source as described in that subdivision. The department shall review and approve the addition of a new source or long-term change in water treatment before it is implemented by the water supply. The department may require the supply to conduct additional monitoring or to take other action the department considers appropriate consistent with the requirements of R325.10604f(2) to ensure the supply maintains minimal levels of corrosion in the distribution system.

(D) & (E).....(lots more but not germane to the discussion)

Subparagraph (C) raises the issue of why Flint's change in source and treatment did not trigger additional department actions. One explanation has to do with whether the City of Flint was *"considered to have optimized corrosion control."* ODWMA staff did not consider Flint or any of the almost 300 other consecutive, customer water systems in Michigan that only receive and distribute finished water to be responsible for corrosion control treatment. It has been our practice to consider treatment of water to be the responsibility of the wholesale supplier, in this case DWSD. Therefore, this rule was not

considered applicable. Another explanation is that Flint already had authority to use the Flint River based on historic permits and periodic emergency use, so the city was not required to seek DEQ approval for a "new" source. And like every other large water system that initially came under the jurisdiction of the lead and copper rules, we were applying the overall procedure described in the above paragraph above subparagraphs (A) through (E) that allowed a system to demonstrate whether their current treatment methods were already deemed optimal. When the LCR was first implemented, numerous systems exceeded the lead action level of 15 ppb and wholesale suppliers had to optimize the corrosion control treatment. Under the regulatory framework allowed, some systems went 4 or more years before they had optimized their corrosion control, and in some cases, it took longer for it to take full effect in all of the consecutive customer supplies.

City of Flint Drinking Water
Outline prepared by the
Michigan Department of Environmental Quality for the
Flint Water Task Force

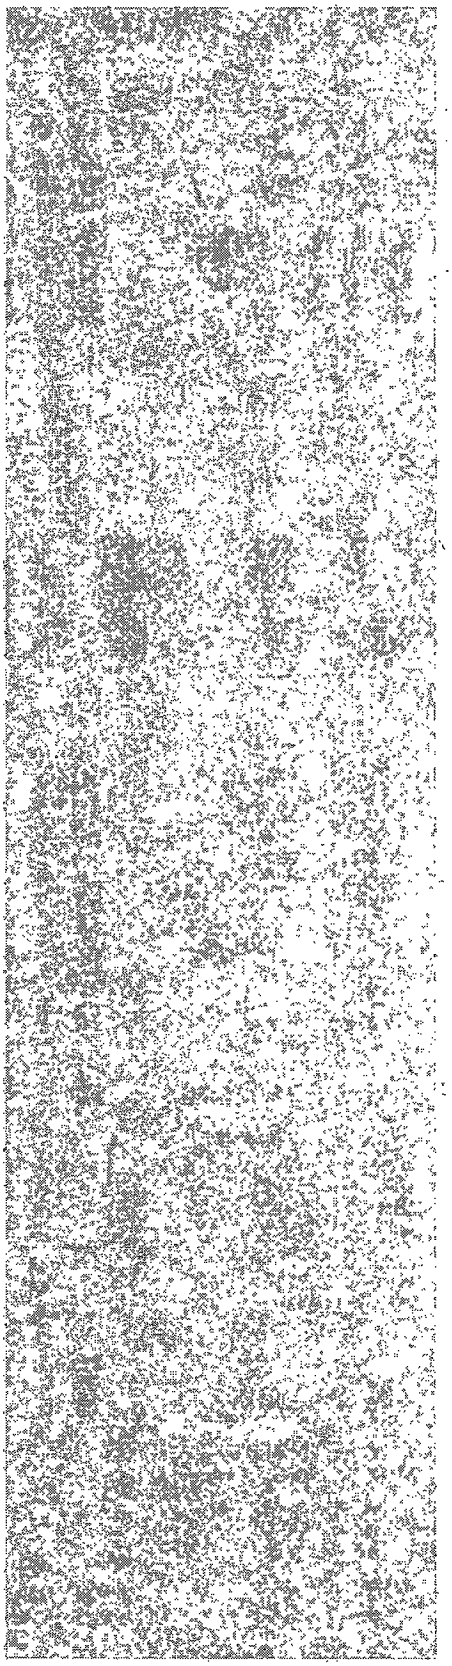
I. INTRODUCTION

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), with respect to events in the city of Flint (City), Michigan.

II. BACKGROUND

1. How has Flint historically obtained its drinking water?

The water system in the City was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City. In 1967, the City switched and became a customer of the Detroit Water and Sewerage Department (DWSD) system.



After the switch to DWSD, the City operated their water treatment plant as a standby plant for purposes of reliability in the event of an emergency such as an interruption in service via the single pipeline from DWSD.

During 2009, the water treatment plant was used in an emergency capacity in two instances: June 18 through June 20 and September 10 through September 13. Additionally, as a backup emergency plant, the City was required to operate the plant quarterly to demonstrate the capability to produce safe water in accordance with Act 399 and to keep mechanical equipment (such as valves, rubber seals, etc.) in good working order. Each quarter, the plant was test run and samples were taken of both raw water and of finished water (post-filters). Monitoring showed that the WTP was performing as designed. However, as a result of contractual obligations with DWSD, this treated water was not put into the City's distribution system during these test runs, but rather was discharged to the river in accordance with a National Pollutant Discharge Elimination System (NPDES) Permit. The test runs were for demonstration purposes, to keep the plant operational, and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules exist to ensure safe drinking water is provided to City residents?

The federal Safe Drinking Water Act (federal SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the federal SDWA, the United States Environmental Protection Agency (USEPA) sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and

1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (The federal SDWA does not regulate private wells which serve fewer than 25 individuals.)

Originally, the federal SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to the USEPA for "primacy," the authority to implement the federal SDWA within their jurisdictions, if they will adopt standards at least as stringent as the USEPA's and enforce those standards. Michigan adopted the Safe Drinking Water Act in 1976 through Act 399 and has maintained primacy for the program since that time.

3. **What is the USEPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the federal SDWA, the USEPA is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards, by working with states.

Michigan's drinking water program is audited annually by the USEPA for compliance with the federal SDWA. Based upon these audits, the USEPA continues to find Michigan's drinking water program to be compliant with the federal SDWA.

4. **What is the Michigan Department of Environmental Quality's (DEQ) role as a regulatory agency in implementing the SDWA?**

The federal SDWA permits states to accept oversight of the drinking water program under an agreement with the USEPA giving states primary enforcement responsibilities (or primacy). In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes. Michigan has had regulatory authority providing oversight of public water supplies since 1913 (Waterworks and Sewerage Systems, Act 98 of 1913).

The DEQ has been granted primary enforcement authority in Michigan for the federal SDWA under the statutory authority of Act 399. As such, the DEQ, Office of Drinking Water and Municipal Assistance (ODWMA) has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies. A community water supply provides year-round service to 15 or more living units or 25 or more residents. A noncommunity water supply has 15 or more service connections or serves 25 or more individuals on an average daily basis for not less than 60 days per year.

The DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: conducting surveillance visits at water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the training, examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; and since 1996, providing financial assistance for system improvements.

5. **What is the City's role in implementing the federal SDWA?**

State and federal programs develop regulations and perform oversight and compliance activities, but do not treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers in compliance with state and federal regulations.

To ensure that drinking water is safe, the federal SDWA sets up multiple barriers against pollution. These barriers include: source water protection, multiple treatment components, distribution system integrity, proper operations oversight, and public information. As a public water system, the City is responsible for ensuring proper design, construction, operations and maintenance, so that contaminants in tap water do not exceed the standards established by law. The City treats the water, and must test their water frequently for specified contaminants and report the results to the DEQ. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The federal SDWA recognizes that customers have the right to know what is in their drinking water and where it comes from. The City, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports (CCR) on the source and quality of their tap water.

The City submits samples of their water for laboratory testing (monitoring) to verify the water they provide to residents meets all federal and state standards. How often and where samples are taken varies from system to system and from contaminant to contaminant. The DEQ provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the City is required to employ properly, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the City's water system.

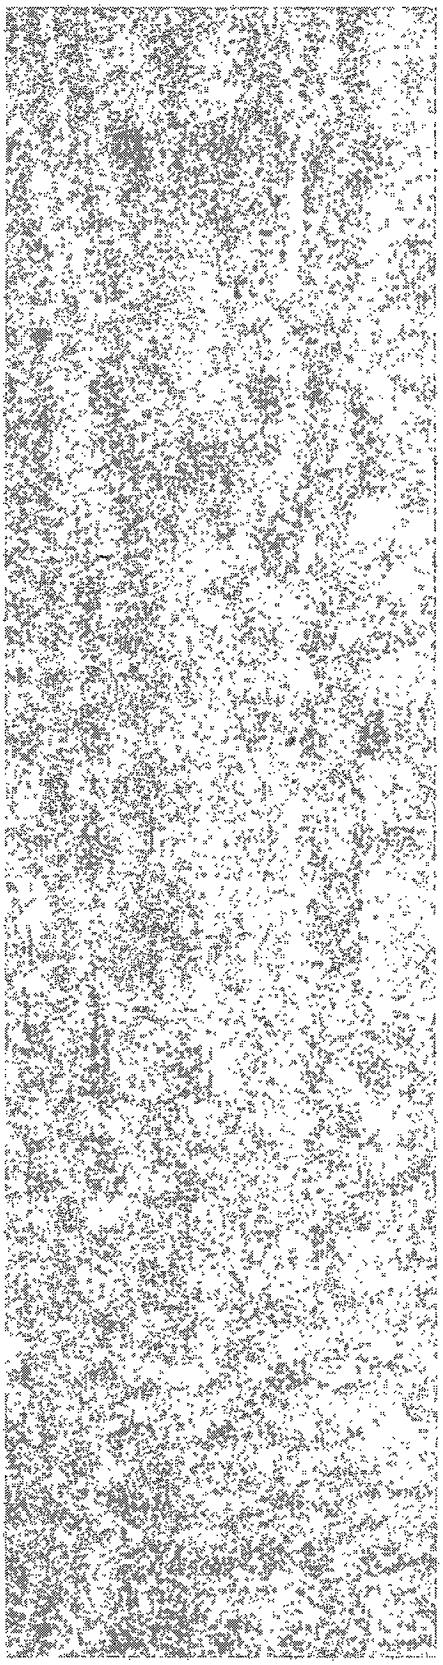
III. THE FLINT RIVER – IS IT A SAFE SOURCE OF DRINKING WATER?

In Michigan, we are fortunate to have high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, the majority of which is withdrawn from the Great Lakes. A handful of public water supplies in Michigan do treat water from inland rivers, lakes or groundwater under the influence of

surface water. All surface water sources and groundwater under the influence of surface water requires significant treatment in order to be safe for consumption. Treatment of surface water is referred to under Act 399 as "complete treatment."

While all surface water sources must receive this higher level of treatment, river sources present a greater challenge than water withdrawn from one of the Great Lakes. River sources are more challenging to treat because of how rapidly water quality may change compared to Great Lakes Sources. Under most circumstances, rivers are also prone to greater fluctuations in temperature, have higher amounts of organic material, greater turbidity (suspended solids), and are more vulnerable to microbiological and viral contamination than Lakes Huron, Erie, Michigan or Superior. It should be noted, that while the water chemistry in the Flint River differs from that in Lake Huron, it can still be treated in accordance with the federal SDWA and Act 399. Many cities across the country rely on similar sources for drinking water. The waterworks industry has the technology to treat wide ranging source waters to provide potable and palatable drinking water, including direct reuse of wastewater. Regardless of source water quality, all public water systems must comply with the same drinking water standards in the finished water.

Also, it is not the source water that reacts with the homeowners plumbing out in the distribution system, but rather the finished water quality that is important. To begin with, neither the Flint River nor the treated water leaving the City's WTP contains lead. In addition, the treatment process employed by the City includes lime softening to reduce the hardness in the river water. Lime softening is not a process that would typically be thought to increase corrosivity of water. The City, however, does practice recarbonation to readjust pH at the end of the softening process. pH levels of finished water leaving the City's WTP averaged 7.7. Water monitoring conducted quarterly at 25 sample sites located throughout the distribution system showed the following:



July – September 2014	average pH = 7.71	range: 7.56 – 7.86
October – December 2014	average pH = 7.88	range: 7.62 – 8.10
January – March 2015	average pH = 7.81	range: 7.60 – 7.99
April – June 2015	average pH = 7.63	range: 7.48 – 7.80

The following data was obtained at the same sampling locations throughout the City's distribution system, but while they were still purchasing water from DWSD before the City switched to the River as a source:

January – March 2014 (DWSD)	average pH = 7.47	range: 7.40 – 7.54
April 2014 (DWSD)	average pH = 7.49	range: 7.42 – 7.59

Note that the pH numbers while the City was treating the Flint River did not differ significantly from those produced by DWSD, and in fact, water produced while using the Flint River tended to be slightly higher (less corrosive).

IV. *E. COLI* AND TOTAL COLIFORM BACTERIA VIOLATIONS

1. **What caused the *E.Coli* and total coliform bacteria violations experienced by the City in August and September 2014?**

   A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWAs) in the City during August and September 2014 triggered by exceedances of bacteria standards in limited areas of the distribution system. While the Flint River has higher levels of natural organic matter than typically found in the Great Lakes, Flint's water treatment plant (WTP) performed well above requirements for removal of organic carbon. In addition, the coliform detections were confined to less than 20 percent of the water system. If treatment had been compromised, detections would have been expected throughout the City rather than in such a limited geographic area.

   Instead, the violations seem to have been caused by other factors such as aging infrastructure and unusual weather patterns. The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of unlined cast iron piping. This cast iron pipe is subject to internal corrosion, called tuberculation, which thins and weakens the pipe walls in some areas and causes a buildup of sediment and debris on the pipe walls in other areas. Tuberculation can lead to water quality issues as well as reduced flows and pressures. Tuberculation also encourages the development of biofilms, or layers of bacteria that attach to the rough surfaces of interior pipe walls. Biofilm growth is common in areas where little or no disinfectant residual is maintained.

   The City has also experienced decades of a declining customer base and water use, with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time (stagnation) within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and loss of disinfectant residual. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been known to improperly use fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination. These hydraulic disturbances were also believed to be the source of the aesthetic water quality complaints both the city and DEQ were receiving.

   The winter of 2013/2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30 percent, saw even greater losses since February of that year due to an increase in cold weather related water main breaks and leaks (City personnel reported 400 water main breaks in calendar year 2014, with greater than 50 percent in the winter quarter). The City has also been lacking a formal maintenance program for its more than 7,250 valves, which are critical in limiting the areas impacted during water main repairs. As an example, two valves on the transmission line used to supply the area of the 2014 BWAs were found to be closed during the City's investigation of possible sources, causing much longer residence times, reduced disinfectant residuals, and reduced pressures – all potential avenues for contamination to enter a distribution system.

   The BWAs also occurred during the warmest and relatively wet periods of August and September 2014. Warm weather conditions are not only more conducive to bacterial

growth but also degrade disinfectant residuals more quickly. As already explained, longer residence times, biofilms, and tuberculation contribute to disinfectant residual degradation. Warm, wet weather conditions also allow water contaminated with bacteria to accumulate or pond around piping that leaks and breaks.

During the summer of 2014, the city was actively repairing the distribution system (City personnel reported 29 water main breaks in June through August 2014). After the switch to the Flint River, it was discovered that there were many broken or closed valves in the distribution system (City personnel reported 120 broken valves and 239 valves in an improper position). As the city began correcting this problem they did detect the presence of coliform organisms in the distribution system in the testing conducted as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected? What was the DEQ's response?

Federal SDWA Regulations regarding monitoring and standards for bacteria in water distribution systems are incorporated into Act 399. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems are required to test for total coliform and *E.coli*. Total coliform bacteria, while not pathogenic, often originate from the same sources as many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system indicates a minimal likelihood that pathogens are present. *E.Coli* is itself a pathogen and its detection is considered direct evidence of a health risk.

The BWAs which occurred in the City were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City collaboratively in consultation with the DEQ.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to rescind a BWA under these circumstances would be expected to take 3 to 4 days.

Upon receiving information indicating total coliform and *E. Coli* bacteria had been detected, DEQ advised the City to issue a BWA from August 15 through 20, 2014, for the affected portion of the City. Another BWA was issued from September 5 through 9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City.

The advisory covered an area approximately 6 square miles or less than 20 percent of the water department's service area of just over 34 square miles.

No total coliform or *E. Coli* bacteria detections have been reported in the City since September 2014.

V. TOTAL TRIHALOMETHANES (TTHM) VIOLATIONS

1. What caused the TTHM violations experienced by the City beginning in late summer 2014?

Disinfectants are an essential element of drinking water treatment because of the barrier they provide against waterborne disease-causing microorganisms. However, disinfection byproducts (DBPs) form when disinfectants used to treat drinking water react with naturally occurring materials in the water (e.g., decomposing plant material). A major challenge for water suppliers is how to control and limit the risks from pathogens and disinfection byproducts. It is important to provide protection from pathogens while simultaneously minimizing health risks to the population from disinfection byproducts.Total Trihalomethanes (TTHM – chloroform, bromoform, bromodichloromethane, and dibromochloromethane) and halogenated acetic acids (HAA5 – monochloro-, dichloro-, trichloro-, monobromo-, dibromo-) are widely occurring classes of DBPs. The amount of TTHM and HAA5 in drinking water from one water system can change from day to day, depending on the season, water temperature, amount of chlorine added, the amount of plant material in the water, and a variety of other factors. All community water systems that chemically disinfect or purchase water that has been chemically disinfected are required to monitor for DBPs.

The Flint River has higher levels of organic material than water in the Great Lakes and as a result the water produced by the City developed higher DBPs than the water provided by DWSD. However, because the WTP was previously operating intermittently as an emergency backup supply with water being wasted rather than entering the distribution system, it was not possible to predict DBP formation until the City began relying on it continuously.

As mentioned previously, the City became aware that there were numerous broken valves and closed valves that should have been open in the distribution system. At this time, the City also began a mapping effort to identify "water age" in the distribution system. The longer the residence time or "water age" the greater the opportunity for the formation of DBPs.

2. How were the violations detected? What was the DEQ's response?

In preparing to rely on the Flint River, the City installed an ozone treatment system to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 maximum contaminant levels (MCLs) are calculated based on a running annual average at specific distribution system locations, the actual violation of the federal SDWA standard did not occur until the fall of 2014. However, it was apparent in the

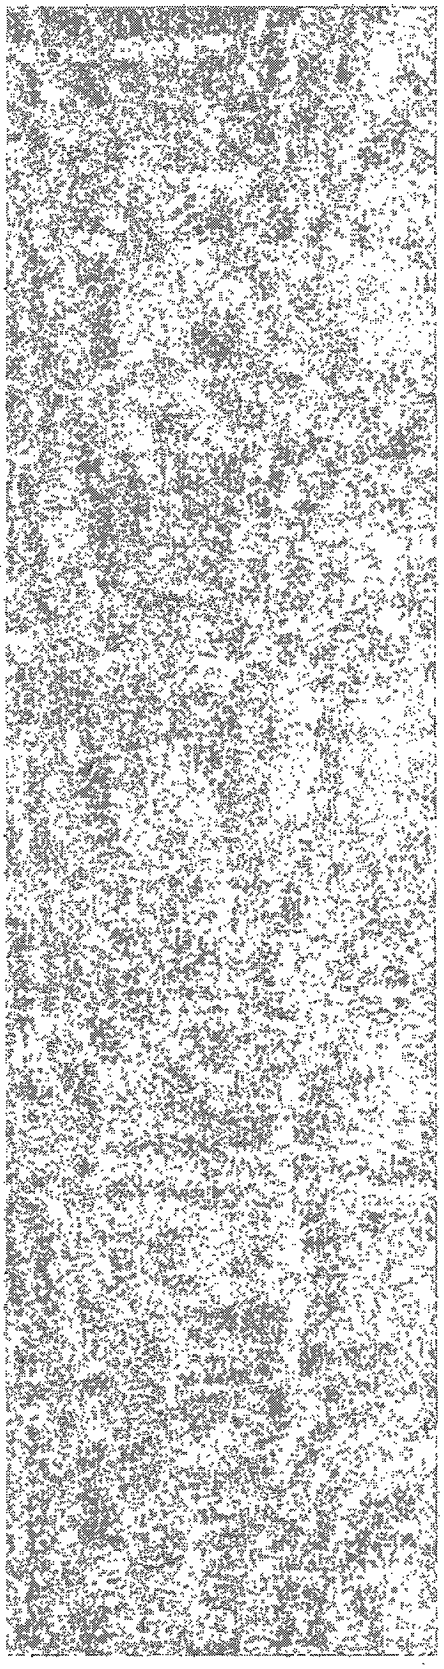
summer of 2014 that the standard would eventually be exceeded; the DEQ asked the City to proactively implement measures to address the problem before the violation required them to do so.

As a result of maintenance efforts undertaken by the City to repair valves and correct improperly closed valves; the City was able to improve hydraulic characteristics of the distribution system and thereby reduce residence time or "water age" in the system. Operational changes made to reduce the amount of storage in the system also helped reduce residence time which contributed to a reduction in DBP formation.

In addition to operational changes to minimize residence time in the distribution system, the City added granular activated carbon to their filters after receiving a construction permit from the DEQ on July 14, 2015. Levels of TTHMs and HAA5s were reduced and the City returned to compliance with the running annual average (MCL) on September 1, 2015.

VI. THE TASTE, ODOR, AND COLOR COMPLAINTS RECEIVED BY FLINT

1. What caused the taste, odor and color complaints received by the City from residents?



Taste, odor and color issues are very personalized. In the City, during the summer after the switch to the Flint River as a water source, taste, odor, and color complaints increased. At the time, increases in color, odor and changes in taste appear to occur because of changes in hydraulic conditions within the distribution system. Water leaving the WTP did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing, and changes in flow characteristics are all known causes of disturbances with the distribution system that can cause an increase in taste, odor and color. Aesthetics, such as taste, odor, and color, while a concern, by themselves are not a threat to public health.

2. What was the DEQ's response?

The DEQ consulted with the City regarding these complaints. The City indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but City personnel informed the DEQ that they were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHMs, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) often causes temporary problems as described. Based on information from City personnel, it appeared that the complaints were related to such operational activities occurring in the distribution system.

VII. LEAD ISSUES IN THE FLINT DRINKING WATER

1. What causes lead in drinking water?

Lead is rarely found in source water. Lead enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead fixtures, and solder. Older homes built prior to World War II, are more likely to contain lead pipes. The most common problem with newer construction is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. Are there any safe levels of lead?

The federal SDWA requires the USEPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLGs). The MCLG for lead is zero. The USEPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

3. What is the Lead and Copper Rule?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, the USEPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 parts per million (ppm) in more than 10 percent of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the AL for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

4. What is the lead action level (AL)?

For most contaminants, the USEPA sets an enforceable regulation called an maximum contaminant level (MCL) based on the MCL Goal (MCLG). MCLs are set as close to the MCLGs as possible, considering cost, benefits, and the ability of public water systems to detect and remove contaminants at the WTP using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, the USEPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to control a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper Rule) requires water systems that produce drinking water to control the corrosivity of the water. The regulation also requires systems to collect customer tap samples from sites served by the system that are more likely to have plumbing materials

containing lead. If more than 10 percent of a system's tap water samples exceed the lead AL of 15 parts per billion (ppb), then water systems are required to take additional actions including:

•Optimizing their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control).

•Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

•Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

5. Did DWSD have a corrosion control plan?

After the LCR passed in 1991, DWSD and all of their consecutive customer systems conducted two rounds of monitoring for lead and copper. Copper levels were well below AL limits, but lead levels exceeded the AL of 15 ppb in Detroit and many of their customer communities. As a result, DWSD installed corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an orthophosphate.

6. Did the DEQ require the City to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. There are two ways under the LCR to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment if it is needed. The DEQ requested that the City perform two 6-month rounds of monitoring to demonstrate if the City was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the City would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the City had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the City had not been the supplier of water before, the DEQ did not require the City to "maintain" corrosion control for which it was not responsible. It could not "maintain" operations undertaken elsewhere by a different entity for a different source of water. The DEQ's instructions to the City were consistent with its past practices and its belief that the City should have been afforded the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full-scale monitoring under the applicable rules. For these reasons, two 6-month

rounds of monitoring, as required by the LCR were the required means to determine whether or not optimal corrosion control was being achieved.

7. How does the DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the procedure below is followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample.
For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Note that the 90th percentile must be interpolated if the number of samples is not a multiple of 10.

8. What was the result of the first round of monitoring conducted by the City?

The first 6-month round of lead and copper monitoring conducted by the City ended on December 31, 2014. One hundred samples were submitted and the 90th percentile lead level was calculated to be 6 ppb.

A 90th percentile lead result of 6 ppb is not unusual and did not approach the AL or cause alarm. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels between 5 ppb and 15 ppb. For example, in 2014, the following communities had lead results as indicated: DWSD (2.3 ppb), Grand Rapids (2.2 ppb), Kalamazoo (13 ppb), Lansing Board of Water and Light (7.8 ppb), and Saginaw (8 ppb).

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the City ended on June 30, 2015. Sixty-nine samples that complied with the site selection criteria submitted and the 90th percentile lead level was calculated to be 11 ppb. The conclusion from these results was that the City, while in compliance with the AL, exceeded the level required to be deemed as having optimized corrosion control.

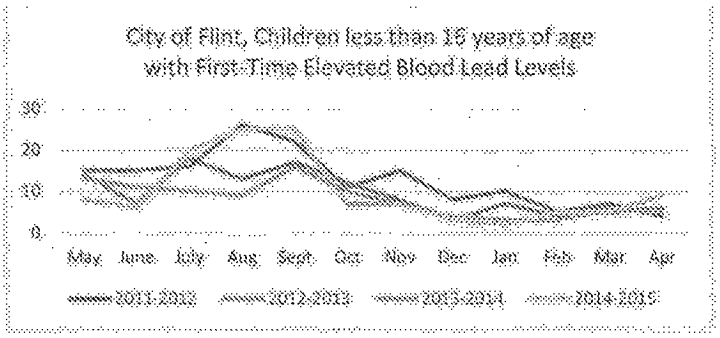
10. Why was the City required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of Act 399.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

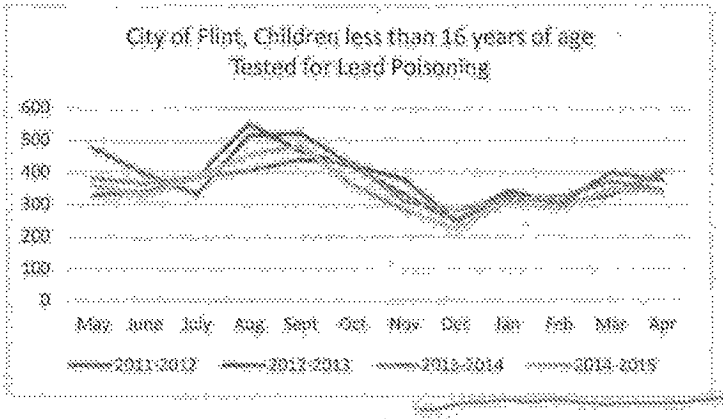
The number of samples the City was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census, which listed the City's population as more than 100,000 residents. In March of 2015, the City provided updated information that indicated the City's population had decreased to less than 100,000. Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

11. What actions did the DEQ order the City to undertake after the second round of monitoring?



While the City's LCR compliance monitoring continued to meet AL requirements, the City exceeded the level required to be deemed as having optimized corrosion control. Following receipt of the City's compliance monitoring results, the DEQ required the City to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the City has 6 months to let the DEQ know whether it intends to conduct a study, then 18 months to perform the study and make their recommendation, and 24 months to complete installation of the selected corrosion control. The DEQ requested the City to accelerate this schedule. The City submitted plans and specifications to install corrosion control treatment and a construction permit was issued by the DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November 2015.



12. What had Department of Health and Human Services (DHHS) advised the DEQ regarding blood lead levels prior to the DEQ ordering the City to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

* Lead testing rates remained about the same from year-to-year (chart on the right).

- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).

- However, that pattern was not terribly different from what we saw in the previous three years; especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).

- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspected that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

This e-mail from DHHS in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City had not exceeded an AL for lead provided

the basis for the DEQ to maintain that the water in the City continued to be in compliance with the federal SDWA and was safe for consumption.

13. When did the DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015, by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by the USEPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August. In early September 2015, information was reported in news articles that pediatricians in the City had data suggesting an increase in children's blood lead levels in two zip codes in the Flint area.

By this time, the City had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment as documented in correspondence dated August 17, 2015.

VIII. QUESTIONS RAISED REGARDING THE DEQ'S ACTIONS

1. What was the DEQ's response to the USEPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by the City under the LCR?

The DEQ indicated that the City was in compliance with the LCR. 90th percentile levels were below the AL of 15 ppb and not unusual when compared to other large Michigan cities. The City was already conducting the second round of monitoring which would provide for a determination of whether additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the LCR that lead results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile AL in the LCR.

2. Did the DEQ attempt to mislead the USEPA in a February 27, 2015, e-mail responding to the USEPA's inquiry regarding Optimal Corrosion Control Treatment (OCCT)?

No. There is an e-mail from Steve Busch indicating that the City was practicing a corrosion control program. What was meant was that the City was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". The DEQ subsequently clarified its position in follow-up telephone conversations with the USEPA.

3. Has the USEPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by the DEQ?

Yes. On November 3, 2015, the USEPA issued a Memorandum to all 50 states regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of OCCT, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The USEPA states that this type of situation rarely arises, that

the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's OCCT procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take or apply in the future. By admitting that the LCR is subject to differing interpretations, the DEQ believes its interpretation and application of the LCR has been validated.

4. Did the DEQ reject any of the samples submitted by the City?

Yes, samples at two locations were excluded from the compliance calculation in conformance with rules issued by the USEPA.

According to the LCR, compliance samples must be a first draw, 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted high-risk sampling sites, called Tier 1 sampling sites. For a municipality such as the City, the Tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

As long as a community has Tier 1 sites that contain lead services, they are required to collect at least 50 percent of their compliance samples from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc.

One of the samples submitted by the City was excluded from the 90th percentile compliance calculation in the latest monitoring period because it was taken from a tap at a non-residential site. The other sample result that was removed was collected from a single family home that has a whole house treatment system. Both of these sites are, therefore, excluded from the compliance consideration based upon federal rules. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point-of-use or point-of-entry treatment can only be used if the community has insufficient Tier 1 sites available.

5. Did the DEQ review the information submitted by the City to ensure all samples were from Tier 1 sites?

Yes. The DEQ examined the information submitted and certified by the City that their LCR sampling pool consisted entirely of lead service lines from single-family homes, which met the requirements of this rule to maximize sampling of high-risk targeted sites.

During the initial implementation of the LCR approximately 25 years ago, water supplies were required to complete a materials evaluation of their distribution system to identify a pool of targeted, high-risk sampling sites. These sites were to be categorized into one of

three tiers (1, 2, or 3) based on risk. The DEQ created an LCR reporting template for water systems to identify each compliance sampling site by Tier, and if they are in the highest Tier (1), to indicate why these sites qualify by having a lead service line, or because they either have copper piping installed with high lead content solder or they have lead plumbing in the home.

If a water system has sufficient Tier 1 sites, they are required to sample them before using any lower tier sites. Furthermore, if they have sufficient sampling sites with lead service lines, they are required to use them to make up at least 50 percent of their sampling pool each monitoring period. Water supplies are also required to use the same sampling sites each time or explain on their LCR reporting form why they were unable to do so. Finally, we require the water system to certify all of the information they provide on the LCR reporting form is factual.

The DEQ must rely upon the public water system to identify appropriate sampling sites for LCR monitoring. The DEQ public water supply program has no control or authority over service lines or domestic plumbing. As a result, we have no records on construction standards or materials used by customers for these components. If these records exist, they are kept locally where they are reviewed and approved by local agencies such as building departments or plumbing inspectors.

In 2015, City employees again certified that the information submitted on their LCR monitoring reports for the two 6-month rounds of monitoring conducted after they began treating the Flint River were accurate, and DEQ staff review of that information indicated it was in compliance with the monitoring requirements. It was not until October 2015 when the DEQ heard City employees revealing to the media that they did not know for certain if their compliance monitoring was collected from homes with lead service lines. As a result, the DEQ began to investigate their monitoring sites. As the City began to transfer their customer information to electronic records, the DEQ determined from the information available that a significant number of these sites that had been listed as having lead service lines either did not have them or the information was unavailable. On November 9, 2015, the DEQ notified the City in writing that it would be necessary to conduct a complete assessment of their sampling pool and report back their findings within a month. The DEQ is now awaiting the City's report.

Comment [LJSS1]: Need to check this date

6. **Did the DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The City replaced the lead service line May 6, 2015. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem, and subsequent sampling taken at this address showed that replacement of the service line did mitigate the problem. There was, therefore, no reason to believe that this was indicative of a system-wide problem.

7. Do the DEQ's sampling instructions comply with the LCR?

We continue to disagree with the USEPA on sampling protocols. We have attempted to ensure compliance with the USEPA's guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, we had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was the USEPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in compliance calculations. Subsequently, the USEPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, we devised our current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

We continue to believe it is appropriate to flush these taps the day before sample collection to simulate and/or ensure typical household use before the tap is allowed to sit overnight to achieve the expected stagnation time (the regulation recommends a minimum 6 hours stagnation prior to collecting the first draw sample). The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. Until the USEPA changes this rule, we are satisfied with our sampling protocol.

8. Does the DEQ require the use of small-neck bottles to obtain samples?

No. The DEQ does not mandate the use of small-neck bottles; it is the sampling method that is specified in both the federal SDWA and Act 399. Each certified drinking water laboratory provides bottles to their customers upon request for any particular analysis. The bottles provided by the DEQ Drinking Water Laboratory for a lead and copper corrosion control sample do happen to have a small cap opening.

9. Why did the DEQ admit mistakes and apologize?

The mounting Freedom of Information Act Requests brought to the director's attention, information from within the DEQ that was not previously known to Director Dan Wyant– specifically, that the USEPA field staff had raised the question of corrosion control in the spring of 2015 and had been critical of the DEQ's protocol and testing process. It seemed clear that the USEPA field staff had opined that DEQ staff had employed the incorrect protocol. In the face of that new information, Direct Wyant felt compelled to acknowledge that an error may have been made as part of moving the conversation and the situation forward.

The subsequent acknowledgement by the USEPA's regional and headquarters leadership that the LCR speaks ambiguously on the issue of continued corrosion control, and that the DEQ did not employ a protocol that was 'wrong,' was of considerable consolation to the DEQ staff but only left agency leadership feeling more resolute that the LCR needs to be changed, and the DEQ is interested in being part of that process.

Also, there should not have been any disrespect or discredit for those who raised the lead in water issue in Flint. For a tone that did not recognize the seriousness or the issue, Director Wyant did apologize.

City of Flint Drinking Water
Outline prepared by the
Michigan Department of Environmental Quality for the
Flint Water Task Force

I. INTRODUCTION

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), with respect to events in the city of Flint (City), Michigan.

II. BACKGROUND

1. How has Flint historically obtained its drinking water?

The water system in the City was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City. In 1967, the City switched and became a customer of the Detroit Water and Sewerage Department (DWSD) system.

After the switch to DWSD, the City operated their water treatment plant as a standby plant for purposes of reliability in the event of an emergency such as an interruption in service via the single pipeline from DWSD.

During 2009, the water treatment plant was used in an emergency capacity in two instances: June 18 through June 20 and September 10 through September 13. Additionally, as a backup emergency plant, the City was required to operate the plant quarterly to demonstrate the capability to produce safe water in accordance with Act 399 and to keep mechanical equipment (such as valves, rubber seals, etc.) in good working order. Each quarter, the plant was test run and samples were taken of both raw water and of finished water (post-filters). Monitoring showed that the WTP was performing as designed. However, as a result of contractual obligations with DWSD, this treated water was not put into the City's distribution system during these test runs, but rather was discharged to the river in accordance with a National Pollutant Discharge Elimination System (NPDES) Permit. The test runs were for demonstration purposes, to keep the plant operational, and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules exist to ensure safe drinking water is provided to City residents?

The federal Safe Drinking Water Act (federal SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the federal SDWA, the United States Environmental Protection Agency (USEPA) sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and

1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (The federal SDWA does not regulate private wells which serve fewer than 25 individuals.)

Originally, the federal SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to the USEPA for "primacy," the authority to implement the federal SDWA within their jurisdictions, if they will adopt standards at least as stringent as the USEPA's and enforce those standards. Michigan adopted the Safe Drinking Water Act in 1976 through Act 399 and has maintained primacy for the program since that time.

3. **What is the USEPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the federal SDWA, the USEPA is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards, by working with states.

Michigan's drinking water program is audited annually by the USEPA for compliance with the federal SDWA. Based upon these audits, the USEPA continues to find Michigan's drinking water program to be compliant with the federal SDWA.

4. **What is the Michigan Department of Environmental Quality's (DEQ) role as a regulatory agency in implementing the SDWA?**

The federal SDWA permits states to accept oversight of the drinking water program under an agreement with the USEPA giving states primary enforcement responsibilities (or primacy). In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes. Michigan has had regulatory authority providing oversight of public water supplies since 1913 (Waterworks and Sewerage Systems, Act 98 of 1913).

The DEQ has been granted primary enforcement authority in Michigan for the federal SDWA under the statutory authority of Act 399. As such, the DEQ, Office of Drinking Water and Municipal Assistance (ODWMA) has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies. A community water supply provides year-round service to 15 or more living units or 25 or more residents. A noncommunity water supply has 15 or more service connections or serves 25 or more individuals on an average daily basis for not less than 60 days per year.

The DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: conducting surveillance visits at water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the training, examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; and since 1996, providing financial assistance for system improvements.

5. **What is the City's role in implementing the federal SDWA?**

State and federal programs develop regulations and perform oversight and compliance activities, but do not treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers in compliance with state and federal regulations.

To ensure that drinking water is safe, the federal SDWA sets up multiple barriers against pollution. These barriers include: source water protection, multiple treatment components, distribution system integrity, proper operations oversight, and public information. As a public water system, the City is responsible for ensuring proper design, construction, operations and maintenance, so that contaminants in tap water do not exceed the standards established by law. The City treats the water, and must test their water frequently for specified contaminants and report the results to the DEQ. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The federal SDWA recognizes that customers have the right to know what is in their drinking water and where it comes from. The City, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports (CCR) on the source and quality of their tap water.

The City submits samples of their water for laboratory testing (monitoring) to verify the water they provide to residents meets all federal and state standards. How often and where samples are taken varies from system to system and from contaminant to contaminant. The DEQ provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the City is required to employ properly, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the City's water system.

III. THE FLINT RIVER – IS IT A SAFE SOURCE OF DRINKING WATER?

In Michigan, we are fortunate to have high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, the majority of which is withdrawn from the Great Lakes. A handful of public water supplies in Michigan do treat water from inland rivers, lakes or groundwater under the influence of

surface water. All surface water sources and groundwater under the influence of surface water requires significant treatment in order to be safe for consumption. Treatment of surface water is referred to under Act 399 as "complete treatment."

While all surface water sources must receive this higher level of treatment, river sources present a greater challenge than water withdrawn from one of the Great Lakes. River sources are more challenging to treat because of how rapidly water quality may change compared to Great Lakes sources. Under most circumstances, rivers are also prone to greater fluctuations in temperature, have higher amounts of organic material, greater turbidity (suspended solids), and are more vulnerable to microbiological and viral contamination than Lakes Huron, Erie, Michigan or Superior. It should be noted, that while the water chemistry in the Flint River differs from that in Lake Huron, it can still be treated in accordance with the federal SDWA and Act 399. Many cities across the country rely on similar sources for drinking water. The waterworks industry has the technology to treat wide ranging source waters to provide potable and palatable drinking water, including direct reuse of wastewater. Regardless of source water quality, all public water systems must comply with the same drinking water standards in the finished water.

Also, it is not the source water that reacts with the homeowners plumbing out in the distribution system, but rather the finished water quality that is important. ~~To begin with,~~ Neither the Flint River nor the treated water leaving the City's WTP contains lead. In addition, the treatment process employed by the City includes lime softening to reduce the hardness in the river water. Lime softening is not a process that would typically be thought to increase corrosivity of water. The City, however, does practice recarbonation to readjust pH at the end of the softening process. pH levels of finished water leaving the City's WTP averaged 7.7. Water monitoring conducted quarterly at 25 sample sites located throughout the distribution system showed the following:

July – September 2014	average pH = 7.71	range: 7.56 – 7.86
October – December 2014	average pH = 7.88	range: 7.62 – 8.10
January – March 2015	average pH = 7.81	range: 7.60 – 7.99
April – June 2015	average pH = 7.63	range: 7.48 – 7.80

The following data was obtained at the same sampling locations throughout the City's distribution system, but while they were still purchasing water from DWSD before the City switched to the River as a source:

January – March 2014 (DWSD)	average pH = 7.47	range: 7.40 – 7.54
April 2014 (DWSD)	average pH = 7.49	range: 7.42 – 7.59

Note that the pH ~~numbers~~ while the City was treating the Flint River did not differ significantly from those produced by DWSD, and in fact, water produced while using the Flint River ~~tended to be slightly higher (less corrosive).~~

IV. *E. COLI* AND TOTAL COLIFORM BACTERIA VIOLATIONS

1. **What caused the *E.Coli* and total coliform bacteria violations experienced by the City in August and September 2014?**

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWAs) in the City during August and September 2014 triggered by exceedances of bacteria standards in limited areas of the distribution system. ~~While the Flint River has higher levels of natural organic matter than typically found in the Great Lakes, Flint's water treatment plant (WTP) performed well above requirements for removal of organic carbon.~~ ~~In addition,~~ the coliform detections were confined to less than 20 percent of the water system. If treatment had been compromised, detections would have been expected throughout the City rather than in such a limited geographic area.

delete ? ✓

Instead, the violations seem to have been caused by other factors such as aging infrastructure and unusual weather patterns. The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of unlined cast iron piping. This cast iron pipe is subject to internal corrosion, called tuberculation, which thins and weakens the pipe walls in some areas and causes a buildup of sediment and debris on the pipe walls in other areas. Tuberculation can lead to water quality issues as well as reduced flows and pressures. Tuberculation also encourages the development of biofilms, or layers of bacteria that attach to the rough surfaces of interior pipe walls. Biofilm growth is common in areas where little or no disinfectant residual is maintained.

water age

The City has also experienced decades of a declining customer base and water use, with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time (stagnation) within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and loss of disinfectant residual. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been known to improperly use fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination. These hydraulic disturbances were also believed to be the source of the aesthetic water quality complaints both the city and DEQ were receiving.

The winter of 2013/2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30 percent, saw even greater losses since February of that year due to an increase in cold weather related water main breaks and leaks (City personnel reported 400 water main breaks in calendar year 2014, with greater than 50 percent in the winter quarter). The City has also been lacking a formal maintenance program for its more than 7,250 valves, which are critical in limiting the areas impacted during water main repairs. As an example, two valves on the transmission line used to supply the area of the 2014 BWAs were found to be closed during the City's investigation of possible sources, causing much longer residence times, reduced disinfectant residuals, and reduced pressures – all potential avenues for contamination to enter a distribution system.

The BWAs also occurred during the warmest and relatively wet periods of August and September 2014. Warm weather conditions are not only more conducive to bacterial

growth but also degrade disinfectant residuals more quickly. As already explained, longer residence times, biofilms, and tuberculation contribute to disinfectant residual degradation. Warm, wet weather conditions also allow water contaminated with bacteria to accumulate or pond around piping that leaks and breaks.

During the summer of 2014, the city was actively repairing the distribution system (City personnel reported 29 water main breaks in June through August 2014). After the switch to the Flint River, it was discovered that there were many broken or closed valves in the distribution system (City personnel reported 120 broken valves and 239 valves in an improper position). As the city began correcting this problem they did detect the presence of coliform organisms in the distribution system in the testing conducted as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected? What was the DEQ's response?

2

Federal SDWA Regulations regarding monitoring and standards for bacteria in water distribution systems are incorporated into Act 399. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems are required to test for total coliform and *E.coli*. Total coliform bacteria, while not pathogenic, often originate from the same sources as many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system indicates a minimal likelihood that pathogens are present. *E.Coli* is itself a pathogen and its detection is considered direct evidence of a health risk.

The BWAs which occurred in the City were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City collaboratively in consultation with the DEQ.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using ~~the most common~~ analytical methods, samples must be incubated for 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to rescind a BWA under these circumstances would be expected to take 3 to 4 days.

approved

Upon receiving information indicating total coliform and *E. Coli* bacteria had been detected, DEQ advised the City to issue a BWA from August 15 through 20, 2014, for the affected portion of the City. Another BWA was issued from September 5 through 9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City.

The advisory covered an area approximately 6 square miles or less than 20 percent of the water department's service area of just over 34 square miles.

No total coliform or *E. Coli* bacteria detections have been reported in the City since September 2014.

V. TOTAL TRIHALOMETHANES (TTHM) VIOLATIONS

1. What caused the TTHM violations experienced by the City beginning in late summer 2014?

Disinfectants are an essential element of drinking water treatment because of the barrier they provide against waterborne disease-causing microorganisms. However, disinfection byproducts (DBPs) form when disinfectants used to treat drinking water react with naturally occurring materials in the water (e.g., decomposing plant material). A major challenge for water suppliers is how to control and limit the risks from pathogens and disinfection byproducts. It is important to provide protection from pathogens while simultaneously minimizing health risks to the population from disinfection byproducts.Total Trihalomethanes (TTHM – chloroform, bromoform, bromodichloromethane, and dibromochloromethane) and halogenated acetic acids (HAA5 – monochloro-, dichloro-, trichloro-, monobromo-, dibromo-) are widely occurring classes of DBPs. The amount of TTHM and HAA5 in drinking water from one water system can change from day to day, depending on the season, water temperature, amount of chlorine added, the amount of plant material in the water, and a variety of other factors. All community water systems that chemically disinfect or purchase water that has been chemically disinfected are required to monitor for DBPs

The Flint River has higher levels of organic material than water in the Great Lakes and as a result the water produced by the City developed higher DBPs than the water provided by DWSD. However, because the WTP was previously operating intermittently as an emergency backup supply with water being wasted rather than entering the distribution system, it was not possible to predict DBP formation until the City began relying on it continuously.

As mentioned previously, the City became aware that there were numerous broken valves and closed valves that should have been open in the distribution system. At this time, the City also began a mapping effort to identify "water age" in the distribution system. The longer the residence time or "water age" the greater the opportunity for the formation of DBPs.

2. How were the violations detected? What was the DEQ's response?

In preparing to rely on the Flint River, the City installed an ozone treatment system to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 maximum contaminant levels (MCLs) are calculated based on a running annual average at specific distribution system locations, the actual violation of the federal SDWA standard did not occur until the fall of 2014. However, it was apparent in the

summer of 2014 that the standard would eventually be exceeded; the DEQ asked the City to proactively implement measures to address the problem before the violation required them to do so.

As a result of maintenance efforts undertaken by the City to repair valves and correct improperly closed valves; the City was able to improve hydraulic characteristics of the distribution system and thereby reduce residence time or "water age" in the system. Operational changes made to reduce the amount of storage in the system also helped reduce residence time which contributed to a reduction in DBP formation.

In addition to operational changes to minimize residence time in the distribution system, the City added granular activated carbon to their filters after receiving a construction permit from the DEQ on July 14, 2015. Levels of TTHMs and HAA5s were reduced and the City returned to compliance with the running annual average (MCL) on September 1, 2015.

(construction permit required for any entity to place a treatment process)

VI. THE TASTE, ODOR, AND COLOR COMPLAINTS RECEIVED BY FLINT

1. What caused the taste, odor and color complaints received by the City from residents?

Taste, odor and color issues are very personalized. In the City, during the summer after the switch to the Flint River as a water source, taste, odor, and color complaints increased. At the time, increases in color, odor and changes in taste appear to occur because of changes in hydraulic conditions within the distribution system. Water leaving the WTP did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing, and changes in flow characteristics are all known causes of disturbances with the distribution system that can cause an increase in taste, odor and color. Aesthetics, such as taste, odor, and color, while a concern, by themselves are not a threat to public health.

2. What was the DEQ's response?

The DEQ consulted with the City regarding these complaints. The City indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but City personnel informed the DEQ that they were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHMs, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) often causes temporary problems as described. Based on information from City personnel, it appeared that the complaints were related to such operational activities occurring in the distribution system.

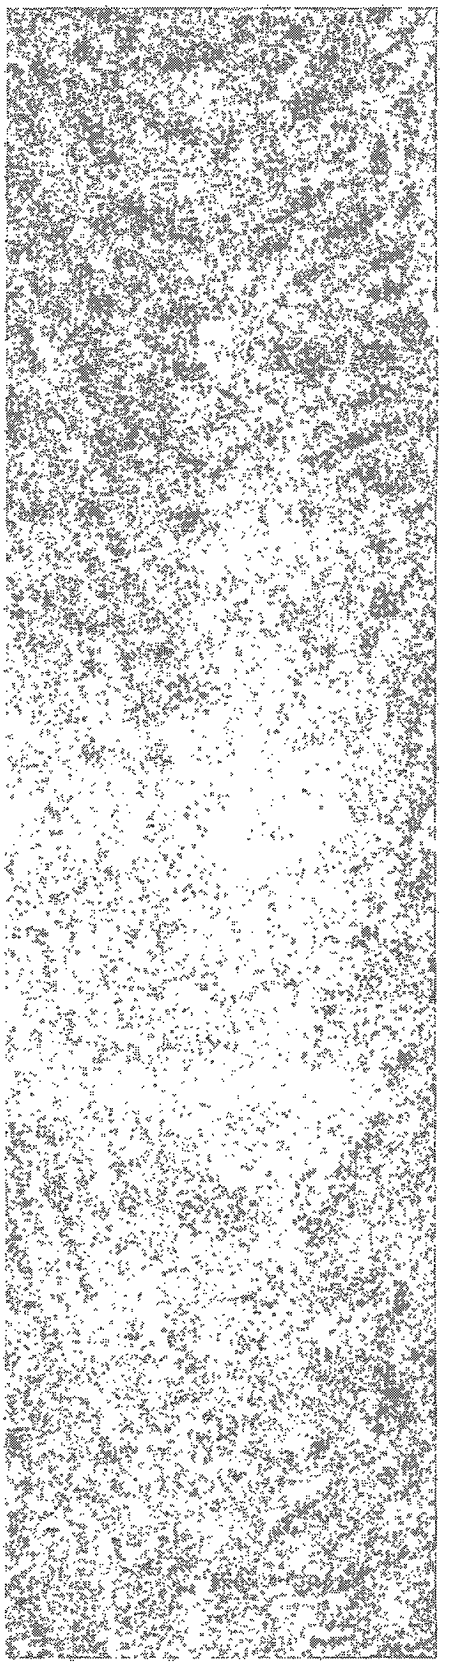
VII. LEAD ISSUES IN THE FLINT DRINKING WATER

1. What causes lead in drinking water?

Lead is rarely found in source water. Lead enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead fixtures, and solder. Older homes built prior to World War II, are more likely to contain lead pipes. The most common problem with newer construction is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. Are there any safe levels of lead?

The federal SDWA requires the USEPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLGs). The MCLG for lead is zero. The USEPA has set this level based on the best available science which shows there is no safe level of exposure to lead.



3. What is the Lead and Copper Rule?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, the USEPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 parts per million (ppm) in more than 10 percent of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the AL for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

4. What is the lead action level (AL)?

For most contaminants, the USEPA sets an enforceable regulation called an maximum contaminant level (MCL) based on the MCL Goal (MCLG). MCLs are set as close to the MCLGs as possible, considering cost, benefits, and the ability of public water systems to detect and remove contaminants at the WTP using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, the USEPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to control a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper Rule) requires water systems that produce drinking water to control the corrosivity of the water. The regulation also requires systems to collect customer tap samples from sites served by the system that are more likely to have plumbing materials

containing lead. If more than 10 percent of a system's tap water samples exceed the lead AL of 15 parts per billion (ppb), then water systems are required to take additional actions including:

•Optimizing their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control).

•Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

•Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

5. Did DWSD have a corrosion control plan?

After the LCR passed in 1991, DWSD and all of their consecutive customer systems conducted two rounds of monitoring for lead and copper. Copper levels were well below AL limits; but lead levels exceeded the AL of 15 ppb in Detroit and many of their customer communities. As a result, DWSD installed corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an orthophosphate.

6. Did the DEQ require the City to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. There are two ways under the LCR to deem a water supply as providing "optimal corrosion control" -- either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment if it is needed. The DEQ requested that the City perform two 6-month rounds of monitoring to demonstrate if the City was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the City would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the City had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the City had not been the supplier of water before, the DEQ did not require the City to "maintain" corrosion control for which it was not responsible. It could not "maintain" operations undertaken elsewhere by a different entity for a different source of water. The DEQ's instructions to the City were consistent with its past practices ~~and its belief that the City should have been~~ afforded ~~the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full-scale monitoring under the applicable rules~~. For these reasons, two 6-month

rounds of monitoring, as required by the LCR were the required means to determine whether or not optimal corrosion control was being achieved.

7. How does the DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the procedure below is followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Note that the 90th percentile must be interpolated if the number of samples is not a multiple of 10.

8. What was the result of the first round of monitoring conducted by the City?

The first 6-month round of lead and copper monitoring conducted by the City ended on December 31, 2014. One hundred samples were submitted and the 90th percentile lead level was calculated to be 6 ppb.

A 90th percentile lead result of 6 ppb is not unusual and did not approach the AL or cause alarm. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels between 5 ppb and 15 ppb. For example, in 2014, the following communities had lead results as indicated: DWSD (2.3 ppb), Grand Rapids (2.2 ppb), Kalamazoo (13 ppb), Lansing Board of Water and Light (7.8 ppb), and Saginaw (8 ppb).

6 ppb

90th percentile

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the City ended on June 30, 2015. Sixty-nine samples that complied with the site selection criteria submitted and the 90th percentile lead level was calculated to be 11 ppb. The conclusion from these results was that the City, while in compliance with the AL, exceeded the level required to be deemed as having optimized corrosion control.

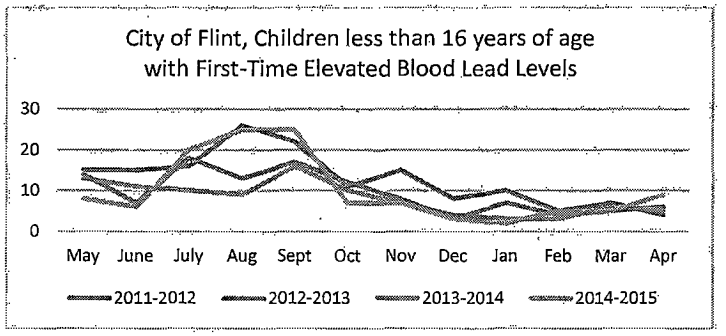
10. Why was the City required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of Act 399.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

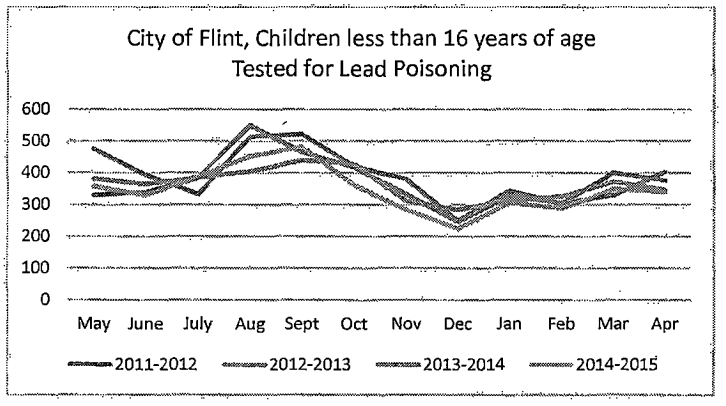
The number of samples the City was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census, which listed the City's population as more than 100,000 residents. In March of 2015, the City provided updated information that indicated the City's population had decreased to less than 100,000. Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

11. What actions did the DEQ order the City to undertake after the second round of monitoring?



While the City's LCR compliance monitoring continued to meet AL requirements, the City exceeded the level required to be deemed as having optimized corrosion control. Following receipt of the City's compliance monitoring results, the DEQ required the City to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the City has 6 months to let the DEQ know whether it intends to conduct a study, then 18 months to perform the study and make their recommendation, and 24 months to complete installation of the selected corrosion control. The DEQ requested the City to accelerate this schedule. The City submitted plans and specifications to install corrosion control treatment and a construction permit was issued by the DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November 2015.



12. What had Department of Health and Human Services (DHHS) advised the DEQ regarding blood lead levels prior to the DEQ ordering the City to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

* Lead testing rates remained about the same from year-to-year (chart on the right).

- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).

- However, that pattern was not terribly different from what we saw in the previous three years; especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).

- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspected that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

This e-mail from DHHS in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City had not exceeded an AL for lead provided

the basis for the DEQ to maintain that the water in the City continued to be in compliance with the federal SDWA and was safe for consumption.

13. When did the DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015, by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by the USEPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August. In early September 2015, information was reported in news articles that pediatricians in the City had data suggesting an increase in children's blood lead levels in two zip codes in the Flint area.

By this time, the City had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment as documented in correspondence dated August 17, 2015.

VIII. QUESTIONS RAISED REGARDING THE DEQ'S ACTIONS

1. What was the DEQ's response to the USEPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by the City under the LCR?

The DEQ indicated that the City was in compliance with the LCR. 90th percentile levels were below the AL of 15 ppb and not unusual when compared to other large Michigan cities. The City was already conducting the second round of monitoring which would provide for a determination of whether additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the LCR that lead results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile AL in the LCR.

2. Did the DEQ attempt to mislead the USEPA in a February 27, 2015, e-mail responding to the USEPA's inquiry regarding Optimal Corrosion Control Treatment (OCCT)?

No. There is an e-mail from Steve Busch indicating that the City was practicing a corrosion control program. What was meant was that the City was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". The DEQ subsequently clarified its position in follow-up telephone conversations with the USEPA.

3. Has the USEPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by the DEQ?

Yes. On November 3, 2015, the USEPA issued a Memorandum to all 50 states regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of OCCT, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The USEPA states that this type of situation rarely arises, that

the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's OCCT procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take or apply in the future. By admitting that the LCR is subject to differing interpretations, the DEQ believes its interpretation and application of the LCR has been validated.

4. Did the DEQ reject any of the samples submitted by the City?

Yes, samples at two locations were excluded from the compliance calculation in conformance with rules issued by the USEPA.

According to the LCR, compliance samples must be a first draw, 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted high-risk sampling sites, called Tier 1 sampling sites. For a municipality such as the City, the Tier 1 sampling pool must consist of single family structures that are:

* served by a lead service line,
* contain lead pipes, or
* contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

As long as a community has Tier 1 sites that contain lead services, they are required to collect at least 50 percent of their compliance samples from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc.

One of the samples submitted by the City was excluded from the 90th percentile compliance calculation in the latest monitoring period because it was taken from a tap at a non-residential site. The other sample result that was removed was collected from a single family home that has a whole house treatment system. Both of these sites are, therefore, excluded from the compliance consideration based upon federal rules. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point-of-use or point-of-entry treatment can only be used if the community has insufficient Tier 1 sites available.

5. Did the DEQ review the information submitted by the City to ensure all samples were from Tier 1 sites?

Yes. The DEQ examined the information submitted and certified by the City that their LCR sampling pool consisted entirely of lead service lines from single-family homes, which met the requirements of this rule to maximize sampling of high-risk targeted sites.

During the initial implementation of the LCR approximately 25 years ago, water supplies were required to complete a materials evaluation of their distribution system to identify a pool of targeted, high-risk sampling sites. These sites were to be categorized into one of

three tiers (1, 2, or 3) based on risk. The DEQ created an LCR reporting template for water systems to identify each compliance sampling site by Tier, and if they are in the highest Tier (1), to indicate why these sites qualify by having a lead service line, or because they either have copper piping installed with high lead content solder or they have lead plumbing in the home.

If a water system has sufficient Tier 1 sites, they are required to sample them before using any lower Tier sites. Furthermore, if they have sufficient sampling sites with lead service lines, they are required to use them to make up at least 50 percent of their sampling pool each monitoring period. Water supplies are also required to use the same sampling sites each time or explain on their LCR reporting form why they were unable to do so. Finally, we require the water system to certify all of the information they provide on the LCR reporting form is factual.

The DEQ must rely upon the public water system to identify appropriate sampling sites for LCR monitoring. The DEQ public water supply program has no control or authority over service lines or domestic plumbing. As a result, we have no records on construction standards or materials used by customers for these components. If these records exist, they are kept locally where they are reviewed and approved by local agencies such as building departments or plumbing inspectors.

In 2015, City employees again certified that the information submitted on their LCR monitoring reports for the two 6-month rounds of monitoring conducted after they began treating the Flint River were accurate, and DEQ staff review of that information indicated it was in compliance with the monitoring requirements. It was not until ~~October 2015 when the~~ DEQ heard City employees revealing to the media that they did not know for certain if their compliance monitoring was collected from homes with lead service lines. As a result, the DEQ began to investigate their monitoring sites. As the City began to transfer their customer information to electronic records, the DEQ determined from the information available that a significant number of these sites that had been listed as having lead service lines either did not have them or the information was unavailable. On November 9, 2015, the DEQ notified the City in writing that it would be necessary to conduct a complete assessment of their sampling pool and report back their findings ~~within a month~~ by Dec. 30, 2015. The DEQ is now awaiting the City's report.

Comment [LJS1]: Need to check this date

6. **Did the DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**

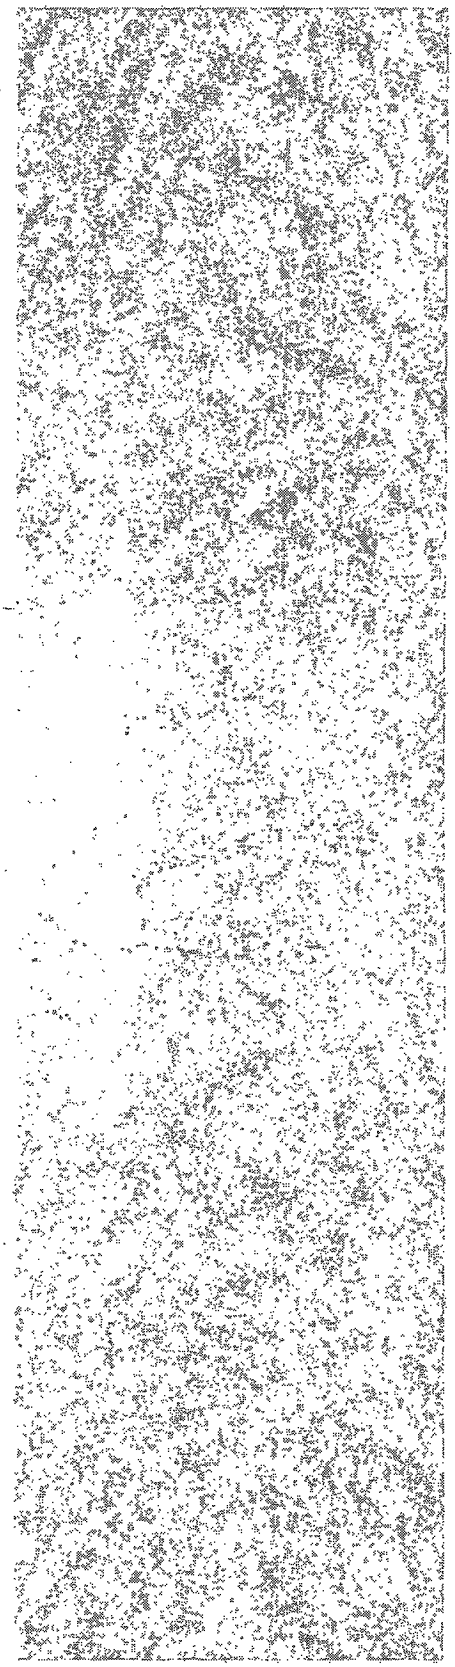
High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The City replaced the lead service line May 6, 2015. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem, and subsequent sampling taken at this address showed that replacement of the service line did mitigate the problem. There was, therefore, no reason to believe that this was indicative of a system-wide problem.

7. Do the DEQ's sampling instructions comply with the LCR?

We continue to disagree with the USEPA on sampling protocols. We have attempted to ensure compliance with the USEPA's guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, we had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was the USEPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in compliance calculations. Subsequently, the USEPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, we devised our current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

We continue to believe it is appropriate to flush these taps the day before sample collection to simulate and/or ensure typical household use before the tap is allowed to sit overnight to achieve the expected stagnation time (the regulation recommends a minimum 6 hours stagnation prior to collecting the first draw sample). The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. Until the USEPA changes this rule, we are satisfied with our sampling protocol.

8. Does the DEQ require the use of small-neck bottles to obtain samples?



No. The DEQ does not mandate the use of small-neck bottles; it is the sampling method that is specified in both the federal SDWA and Act 399. Each certified drinking water laboratory provides bottles to their customers upon request for any particular analysis. The bottles provided by the DEQ Drinking Water Laboratory for a lead and copper corrosion control sample do happen to have a small cap opening.

9. Why did the DEQ admit mistakes and apologize?

The mounting Freedom of Information Act Requests brought to the director's attention, information from within the DEQ that was not previously known to Director Dan Wyant– specifically, that the USEPA field staff had raised the question of corrosion control in the spring of 2015 and had been critical of the DEQ's protocol and testing process. It seemed clear that the USEPA field staff had opined that DEQ staff had employed the incorrect protocol. In the face of that new information, Direct Wyant felt compelled to acknowledge that an error may have been made as part of moving the conversation and the situation forward.

The subsequent acknowledgement by the USEPA's regional and headquarters leadership that the LCR speaks ambiguously on the issue of continued corrosion control, and that the DEQ did not employ a protocol that was 'wrong,' was of considerable consolation to the DEQ staff but only left agency leadership feeling more resolute that the LCR needs to be changed, and the DEQ is interested in being part of that process.

Also, there should not have been any disrespect or discredit for those who raised the lead in water issue in Flint. For a tone that did not recognize the seriousness or the issue, Director Wyant did apologize.

portions of the City of Flint. The advisory covered an area approximately 6 square miles. The City of Flint has a total land area just over 34 square miles.

No total coliform or E.Coli bacteria detections have been reported in Flint since September 2014.

V. TTHM violations

1. What caused the TTHM violations experienced by Flint beginning in late Summer 2014?

Disinfectants are an essential element of drinking water treatment because of the barrier they provide against waterborne disease-causing microorganisms. However, disinfection byproducts (DBPs) form when disinfectants used to treat drinking water react with naturally occurring materials in the water (e.g., decomposing plant material).

Total trihalomethanes (TTHM – chloroform, bromoform, bromodichloromethane, and dibromochloromethane) and haloacetic acids (HAA5 – monochloro-, dichloro-, trichloro-, monobromo-, dibromo-) are widely occurring classes of DBPs. The amount of trihalomethanes and haloacetic acids in drinking water from one water system can change from day to day, depending on the season, water temperature, amount of chlorine added, the amount of plant material in the water, and a variety of other factors. All community water systems that chemically disinfect or purchase water that has been chemically disinfected are required to monitor for DBPs.

~~TTHMs and HAA5s are the result of organic material in the water reacting with disinfectant used to treat the water.~~ The Flint River has higher levels of organic material than water in the Great Lakes and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products than the water provided by DWSD. However, because the water treatment plant was previously operating intermittently as an emergency backup supply, it was not possible to predict disinfection byproduct formation until the city began relying on it continuously.

Comment [KR(2]: Need to explain that TTHM and HAA5s are. Are they hazardous to public health? Same for disinfection by-products. This is a pretty technical read – can we add plain English or more explanation?

Comment [KR(3]: During our interviews, we received a number of comments that the major problem was because the organic level did not have time to stabilize before being discharged into the system and their stagnation in the system exacerbated the problem. Just passing on that info.

2. How were the violations detected and what was DEQ's response?

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the actual violation of ~~city didn't actually violate~~ the safe drinking water act standard for TTHM did not occur until the fall of 2014, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, DEQ asked the city ~~was asked~~ to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on September 1, 2015.

Subject: Media Contact - Flint DW Chloride - Michigan Radio NPR

I was just contacted by Kate Wells, Michigan Radio NPR regarding the recent news about General Motors concerns regarding chloride levels in Flint's Drinking Water.

I explained that chloride does have a secondary level set by EPA which is not for health related issues but rather for taste and aesthetic concerns. Chloride which can generally come from salt, NaCl, sodium chloride, is a normal part of people's diets, and the amounts in Flint's drinking water would likely be minor compared to normal dietary intakes.

She asked about how chloride could be causing corrosion issues at GM. I indicated that I wasn't sure how they were utilizing the water or what their process consisted of. I did indicate that we normally look at other parameters in drinking water such as pH and alkalinity when considering its corrosivity.

She asked about where water is analyzed. I indicated that most chemical analysis is performed at a certified laboratory, and that Flint has generally used the State Drinking Water Lab. She asked about how results are reported and I said that results go back to the system which then provides results to the DEQ, and that the State DW lab will report directly to the DEQ in addition to the City.

She asked about consumer confidence reports (CCRs). I explained that these are federal requirements for all Community Water Systems. I informed her that detections for regulated contaminants would be reported but that with the exception of sodium, unregulated contaminants such as chloride are not required to be reported. That sodium is included so people with low sodium diets can determine their intake from water. I also clarified that the City's current CCR which had to be issued by July 1 would reflect results from 2013 (when Flint was on DWSD) and that 2014 results would be in the CCR issued in 2015.

She asked whether there would be similar health related issues from chloride as there are with sodium since they are both in salt, but I indicated that I'm not aware of any such issue and that if there were EPA would have asked it to be reported on the CCR and/or established a primary standard for it.

She asked about salt entering water, it's visibility, and I explained that when salt is present in water it will dissolve into sodium and chloride, that it would not be visible in the water, especially at the levels indicated.

DRAFT

City of Flint Drinking Water

Outline prepared by the

Michigan Department of Environmental Quality for the

Flint Water Task Force

I. Introduction

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act with respect to events in the City of Flint.

II. Background

1. How has Flint historically obtained its drinking water?

The water system in Flint, Michigan, was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City until 1967, when the City switched and become a customer of the Detroit Water and Sewerage Department (DWSD) system. After the switch to DWSD, the city of Flint operated their water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD was out of service for any reason.

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Michigan's Safe Drinking Water Act (1976 PA 399) and to keep mechanical equipment in good working order (such as valves, rubber seals, etc.) Each time the plant was test-run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules must be complied with in order to ensure safe drinking water is provided to Flint residents?

The federal Safe Drinking Water Act (SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the SDWA, EPA sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (SDWA does not regulate private wells which serve fewer than 25 individuals.)

The federal SDWA authorizes the United States Environmental Protection Agency (US EPA) to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water. US EPA, states, and water systems then work together to make sure that these standards are met.

Originally, the SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to US EPA for "primacy," the authority to implement SDWA within their jurisdictions, if they ~~can show that they will~~ adopt standards at least as stringent as US EPA's and ~~make sure water systems meet these~~ standards. Michigan adopted the Safe Drinking Water Act in 1976 and maintained primacy for the program since 1978.

3. **What is EPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the Safe Drinking Water Act (SDWA), the U.S. Environmental Protection Agency (US EPA) is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards. Michigan's drinking water program is reviewed annually by U.S. EPA.

4. **What is DEQ role's as a regulatory agency in implementing the SDWA?**

SDWA ~~also~~ allows states to accept oversight of the drinking water program under an agreement with US EPA giving states primary enforcement (or primacy) responsibilities. In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes.

The DEQ has primary enforcement authority in Michigan for the Safe Drinking Water Act under the legislative authority of the Michigan Safe Drinking Water Act (Act 399). As such, the division has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies.

The ~~State of~~ Michigan DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: ~~visiting~~ water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; providing financial assistance for system improvements; and conducting training sessions.

5. **What is Flint's role in implementing the SDWA?**

These federal and state programs are separate from the activities performed by water systems. State and federal programs develop regulations and perform oversight and compliance activities, but do not actually treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers.

To ensure that drinking water is safe, SDWA sets up multiple barriers against pollution. These barriers include: source water protection, treatment, distribution system integrity, and public information. As a public water system, the city of Flint is responsible for ensuring that contaminants in tap water do not exceed the standards. The City treats the water, and must test their water frequently for specified contaminants and report the results to the State. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The SDWA recognizes that since everyone drinks water, everyone has the right to know what's in it and where it comes from. The City of Flint, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports on the source and quality of their tap water.

The city of Flint submits samples of their water for laboratory testing (monitoring) to verify that the water they provide to its residents meets all federal and state standards. How often and where samples are taken varies from system to system and contaminant to contaminant. The State provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the city of Flint is required to maintain on staff, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the city's water system.

III. **The Flint River – it is a safe source of drinking water?**

In Michigan, we are blessed with high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, most with intakes in the Great Lakes. A handful of public water supplies in Michigan do treat water from inland sources such as rivers or groundwater under the influence of surface water. While river sources present a greater challenge for

[Our impression is that the average citizen is under the impression that the river water is corrosive and contains lead – we can address no lead, chloride, and lime issues. Address treatment issues to show that water leaving the plant meet all SDWA

requirements. Ph was same as DWSD. Also sets up point that problems arose after water left plant and was disseminated throughout system]

Put from Intro memo IV.

E. Coli and Total Coliform bacteria violations

1. What caused the E.Coli and Total Coliform bacteria violations experienced by Flint in August-September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWA's) in the City of Flint during August and September 2014. While use of the Flint River increased the amount of natural organic matter in the City's water, the City's water treatment plant (WTP) performed well above treatment requirements for organic carbon removal. In addition, less than 20% of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the City, rather than in such a localized area.

The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30%, saw even greater losses since February due to an increase in cold weather related water main breaks and leaks. The City lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWA were found to be closed during the City's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure.

The BWA's also occurred during the warmest and for 2014 relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were many broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected and what was DEQ's response?

The Boil Water Advisories (BWAs) which occurred in the City of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City of Flint collaboratively in consultation with the DEQ.

Regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the EPA, have been in effect since 1990, and incorporated into the Michigan Safe Drinking Water Act. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for Total coliform and E.coli. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system minimizes the likelihood that pathogens are present. E.Coli is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for a period of 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

A BWA was issued from August 15–20, 2014, for a portion of the City of Flint due to localized detections of total coliform and E.Coli bacteria. Another BWA was issued from September 5-9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City of Flint. The advisory covered an area approximately 6 square miles. The City of Flint has a total land area just over 34 square miles.

Put This Later Doc

V. TTHM violations

1. What caused the TTHM violations experienced by Flint beginning in late Summer 2014?

TTHMs and HAASs are the result of organic material in the water reacting with disinfectant used to treat the water. The Flint River has higher levels of organic material than water in the Great Lakes and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products than the water provided by DWSD. However, because the water treatment plant was previously operating intermittently as an emergency backup supply, it was not possible to predict disinfection byproduct formation until the city began relying on it continuously.

2. How were the violations detected and what was DEQ's response?

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't ~~actually~~ violate the safe drinking water act standard until the fall, ~~but because~~ it was apparent in the summer of 2014 ~~that the standard would eventually be exceeded~~, the city was asked to proactively implement measures to address the ~~problem~~ before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAASs were reduced. The city returned to compliance with the running annual average (MCL) on September 1, 2015.

IV. The taste, odor, and smell complaints received by Flint

1. What caused the taste and odor complaints received by Flint from residents?

Taste and odor issues are very personalized. Some water systems receive complaints because of too much disinfectant. In Flint, during the summer after the switch to the Flint River as a water source, taste and odor complaints increased. ~~It was believed~~ at the time ~~to be the result of~~ changes in hydraulic conditions within the distribution system. Water leaving the water treatment plant did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing and changes in flow characteristics are all know causes of disturbances with the distribution system that can cause an increase in taste and odor ~~complaints.~~

2. What was DEQ's response?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

V. The lead issues in the Flint drinking water

1. What causes lead in drinking water?

Lead is rarely found in source water, but enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead pipes, fixtures and solder. The most common problem is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. Lead can leach into water from pipes, solder, fixtures and faucets (brass), and fittings. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What are the lead action levels?

For most contaminants, EPA sets an enforceable regulation called a maximum contaminant level (MCL) based on the MCLG. MCLs are set as close to the MCLGs as possible, considering cost, benefits and the ability of public water systems to detect and remove contaminants using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, EPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to ensure control of a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper rule) requires water systems to control the corrosivity of the water. The regulation also requires systems to collect tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10% of tap water samples exceed the lead action level of 15 parts per billion, then water systems are required to take additional actions including:

- Taking further steps optimize their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control) .
- Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.
- Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

3. Are there any safe levels of lead?

The SDWA requires EPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLG). The MCLG for lead is zero. EPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

4. What is the LCR?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, EPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 ppm in more than 10% of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the action level for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

5. Did DWSD have a corrosion control plan?

After the LCR was passed, DWSD conducted two rounds of monitoring at for lead and copper. Copper levels were well below action level limits; but lead levels exceeded the action level of 15 parts per billion in many of their customer communities. As a result, DWSD needed to install corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an ortho-phosphate.

6. Did DEQ require Flint to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. The DEQ believed there were two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to call for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were

initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

7. How does DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the following steps are followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Multiples of 10 require no averaging or interpolation.

8. What was the result of the first round of monitoring conducted by Flint?

The first 6-month round of lead and copper monitoring conducted by the city of Flint ended on December 31, 2014. One hundred samples ~~100 samples~~ were submitted and the 90th percentile lead level was calculated to be 6 parts per billion.

A 90th percentile lead result of 6 ppb is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the city of Flint ended on June 30, 2015. Sixty nine samples were submitted and the 90th percentile lead level was calculated to be 11 parts per billion. The conclusion from these results was that the city exceeded the level required to be deemed as having optimized corrosion control but did not exceed the action level of 15 parts per billion.

10. What actions did DEQ order Flint to undertake after the second round of monitoring?

While the City's LCR compliance monitoring continued to meet action level requirements, the LCR requires all large systems (those serving over 50,000 people) to optimize corrosion control regardless of their 90th percentile lead concentration. Following receipt of Flint's compliance monitoring results, the DEQ required the city to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the city has 6 months to let the DEQ know whether it intends to conduct a study, 18 months to perform the study, and 24 months to complete installation of corrosion control. The DEQ has requested the city of Flint to accelerate this schedule. The city submitted plans and specifications to install corrosion control treatment and a construction

permit was issued by DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November.

11. What had DHHS advised DEQ regarding blood lead levels prior to DEQ ordering Flint to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.
- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

Insert GRAPHS?

This e-mail in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City of Flint had not exceeded an action level for lead provided the basis for DEQ to maintain that the water in Flint continued to be in compliance with the SDWA and was safe for consumption.

12. When did DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015 by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by U.S. EPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August.

By this time, the City of Flint had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment in

[Hurley and Edwards all after the fact]

VI. **Questions raised regarding DEQ's actions**

1. **What was DEQ's response to EPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by Flint under the LCR?**

DEQ indicated that the city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether or not second round of monitoring which would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

2. **Did DEQ attempt to mislead EPA in a February 27, 2015 email responding to EPA's inquiry regarding OCCT?**

No. There is an e-mail from Steve Busch indicating that the city was practicing corrosion control. This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

3. **Has EPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by DEQ?**

On November 3, 2015, U.S. EPA issued a Memorandum regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The memo states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take/apply in the future.

4. **Did DEQ reject any of the samples submitted by Flint?**

Yes, samples at two locations were excluded from the compliance calculation.

Compliance samples must be a first draw, 1 liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc. One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has whole house treatment system (check with Steve). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

5. **Did DEQ review the information submitted by Flint to ensure all samples were from Tier 1 sites?**

6. **Did DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. Subsequent sampling taken at this address showed that replacement of the service line mitigated the problem. There was also no reason to believe that this was indicative of a system-wide problem.

7. **Do DEQ's sampling instructions comply with the LCR?**

8. **Does DEQ require the use of small-neck bottles to obtain samples?**

9. **Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?**

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan SDWA.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (check with Steve), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated census that indicated the city's population had decreased to less than 100,000 (check with Steve). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

10. Why did DEQ admit it made a mistake?

Add GH –

Background –

Prior to switching from DWSD, the city of Flint operated a water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD failed.

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Act 399 and to keep mechanical equipment in good working order, such as valves, rubber seals, etc. Each time the plant was test run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

Do we want to note that the original decision was to join KWA and begin receiving water in ~3 years from Lake Huron? It wasn't until DWSD issued a termination notice that caused the city to consider relying on the Flint River in the interim because they could not agree on a contract extension with Detroit.

April 2014: Flint terminates service from DWSD and begins using their water treatment plant full time.

What approvals from DEQ were required to do this?

Because Flint had long ago been issued construction permits for raw water pumps to withdraw water from the Flint River, the city was grandfathered under the Water Withdrawal program as were all existing community public water systems. There were no additional DEQ permissions required.

Under Act 399, Michigan's Safe Drinking Water Act, there are no licenses or permit required to operate. Two construction permits were issues prior to the treatment plant changing from an emergency back-up plant to a full time operation. These permits were for small changes such as new chemical feed equipment, changes to the electrical service, etc.

Summer 2014: Flint experiences several (how many?) water main breaks and has 2 localized (describe) boil water events.

Do we mention the unusually harsh winter that led to an increased number of water main breaks throughout Michigan that year?

Is it unusual for a city to issue boil water advisories? Should the state have been concerned at this point?

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were (how many) broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs.

– DAP2 –

This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

Complaints are being made that there are taste, odor, and color issues since the switch from DWSD; including rashes and hair falling out. Why didn't the state do something?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

Late Summer 2014: Monitoring for TTHM's in the distribution system identifies that the city has elevated levels and will violate the MCL for TTHM's in subsequent monitoring.

How was this handled? Should this have been a sign that it was a mistake to "allow" Flint to switch from DWSD to the Flint River?

Because the water treatment plant was originally upgraded for intermittent, emergency use, it was not possible to predict Disinfection Byproduct formation until the city began relying on it continuously. The Flint River had higher levels of organic material and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products. TTHMs and HAA5s are the result of organic material in the water reacting with the disinfectant. On more than one occasion, DEQ district supervisors and engineers have indicated that continuous use of the Flint River poses an increased microbial risk and an increased risk of disinfection byproducts; will trigger additional regulatory requirements for monitoring; and require significant enhancements at the Flint Water Treatment Plant.

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't actually violate the safe drinking water act standard until the fall, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, the city was asked to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on (date?).

What is the role of DEQ as a regulatory agency implementing the Michigan Safe Drinking Water Act?

What is the role of the City of Flint in water system operation and providing safe drinking water?

Issues around lead/copper:

Why didn't DEQ require a corrosion control plan from the city prior to bringing the water treatment plant on-line in April 2014?

DEQ believed there were two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to call for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

The first round of monitoring conducted July 2014 through December 2014 resulted in a 90th percentile of 6 ppb lead. Why didn't the DEQ require the city take actions at this point?

A 90th percentile lead/copper result of 6 ppb for lead is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

In February, EPA staff inquired about corrosion control and whether the city was providing treatment to control corrosion. What was the DEQ's response?

DEQ indicated that they city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that

lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

An e-mail from Steve Busch indicated that the city was practicing corrosion control. Why was this said?

This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

In April, EPA staff visited Flint and sampled a residence at 212 Browning. High levels of lead were present. Why wasn't this seen as a potential system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. There was also no reason to believe that this matter was anything other than a site specific condition. (may not be so unique in terms of Pb levels)

A draft memo, dated June 24, 2015, from an EPA staff person claimed that DEQ had inappropriately handled the sampling at the city and that corrosion control should have been required before start up. What is DEQ's response to these allegations?

DEQ never received this memo and it is our understanding that EPA never sent us this memo. A copy of the draft document was downloaded from the ACLU website. On June 30th, an e-mail was received from EPA that indicated it was a draft memo that had been shared with the homeowner where sampling occurred and that once management had a chance to review the memo they would provide a final copy to DEQ. A final copy was never received. Also, EPA indicated in this same e-mail that a conference call to discuss the issues raised in the memo was scheduled for July 21st between the agencies.

During the July 21st call, EPA provided a rule citation (for the first time) indicating that ..... DEQ provided their interpretation of the lead/copper rule. EPA indicated that they would consult with their attorneys and seek a clarification regarding the two different interpretations. To date (October 20th), DEQ has not received any feedback from EPA regarding the state's interpretation.

There is on-going criticism that the DEQ provides inappropriate guidance to water supplies regarding pre-flushing of taps prior to lead/copper sampling? Explain DEQ's rationale for doing this.

The lead/copper sampling protocol is designed to standardize sample collection and is not the same protocol that would be used for an exposure assessment. Different sampling is done for different purposes.

Under the lead/copper rule, samples collected must be 'first-draw' 1 liter samples collected from kitchen or bathroom taps at EPA designated, high-risk locations after

overnight stagnation. It is recognized that this may or may not be the highest level of lead that could be found at a residence. However, it does provide the water supplier with information about efficacy of their treatment process and an indication of how the water may be reacting with plumbing in the system.

The lead/copper rule is the only rule that requires compliance monitoring to be performed by homeowners. In order to simplify the instructions and ensure consistent sampling protocol and results, DEQ recommends that a sample tap/outlet be run the night before it is going to be sampled so that the sampling location is representative of a tap experiencing typical household use (as required by the lead/copper rule). Historically, there were problems with homeowners sampling from locations that had not been used for days, weeks or even months. The recommended/required stagnation period under the lead/copper rule is 6 to 18 hours. To accomplish this across the board, DEQ policy is to recommend that the tap be used or use be simulated on the night before it is going to be sampled. EPA has incorporated similar sampling protocols into tap sampling programs at schools and day care centers. (do we want to provide a footnote with a citation to the Milwaukee Westlawn CARE Project?)

If there is a lead service line in the house, then a first draw sample under this condition will not contain water that has sat stagnant for some time in that service line. However, flushing the tap the night before will not likely result in capturing a first draw sample that has sat stagnant in that lead service line because only the tap that is going to be sampled is required to be stagnant. If there is a toilet or a dishwasher nearby, they can still be used. And it is impossible to predict whether there is water in that particular line that has spent any time at all resting quietly for any period of time in the service line and only happens to be poised for withdrawal at that particular tap at that particular moment. Only a site specific evaluation of a household plumbing system along with a site specific calculation of the volume of water in the plumbing system and the volume of water in the lead service line would potentially provide for a sample that has rested in the service line assuming that no water has been used in the house during the entire time of "resting". This level of complexity is not a practical approach for a community to employ or for water systems across the country to accomplish when they must rely upon homeowners to collect samples. The lead/copper rule is imperfect. But the instructions provided by DEQ provide for a consistent sampling protocol that is easily followed by homeowners and results in samples collected that meet the legal requirements of the lead/copper rule and the intention of providing water quality information upon which further regulatory decisions should be made. The lead/copper rule is intended to assist water suppliers with evaluating their treatment process and the effects of the water on plumbing systems. It is not a tool to assess individual exposure.

After the July 21st call with EPA where they provided a regulatory citation and their opinion that the DEQ had not followed the required protocol to require treatment, what steps were taken by DEQ to address the situation?

By the time the July 21st call occurred, the city had completed their two 6-month rounds of lead/copper monitoring. This monitoring showed that the city needed to install corrosion control measures. On August 17th, the DEQ wrote the city requiring the city to perform a study and install corrosion control treatment in accordance with the safe drinking water act. We also recommended Flint significantly accelerate this action and not take the time allotted by the regulations for selecting and installing OCCT.

When DEQ met with city residents on August 4th, they were still saying that the water was safe even after the sampling was done and it showed that corrosion control was necessary. Why the contradiction?

At the time of this meeting, all sampling results to date indicated that lead levels were within typical ranges seen in other water systems and below the Action Level established in the rule. It was acknowledged that the results showed that the city of Flint needed to provide optimal corrosion control treatment and that would soon be required. In addition, data provided by our colleagues at the Department of Health and Human Services indicated that there was no significant change in children's blood lead levels within the city. The evaluation showed that blood lead levels were following historical seasonal patterns and there was no indication of a water contributing to an increase. This provided backup confirmation (at that time) that the path followed was correct.

When the V-T researcher raised the alarm on (date) that the sampling required by DEQ was wrong and that levels of lead in the city were much higher than previously thought, why didn't DEQ investigate these claims and follow up on this information?

DEQ was informed in late August that a study was underway in the city and that samples taken appeared to be much higher than those taken under the lead/copper rule. Since we were not provided information regarding protocol used for the study, the DEQ could not adequately comment on the comparison between the two data sets. It was not however, unexpected that a different sampling protocol could yield higher results. Since the required two 6-month rounds of monitoring had already been completed at this point and the city had been notified of the requirement to install treatment, there were no additional actions deemed necessary by the agency at this point. The city had not exceeded the lead action level, they were actively pursuing treatment on an accelerated schedule, and DHHS information regarding blood lead levels in the city indicated that there was NO significant change since the switch.

Why did DEQ change their position in September and agree that lead is a problem in Flint?

As soon as the DHHS Chief Medical Officer determined that there was a correlation between blood lead levels in children in certain zip codes and the switch to the Flint River, DEQ responded. Actions were taken within a week to address the concerns raised.

Why is DEQ admitting it made a mistake?

If EPA's interpretation is correct and the city of Flint was required to maintain corrosion control and should not have been allowed to switch sources without maintaining corrosion control, this wasn't done. All indications are that the protective coating that was in place as a result of treated water received from DWSD has been eroded and that lead leaching has increased during the time that there hasn't been treatment. This was the mistake. However, DEQ staff acted in good faith. They believed that they were implementing the lead/copper rule appropriately with all of its nuances in sampling and limitation on compliance monitoring. The lead/copper rule establishes a mechanism for a new supply (when not previously serving water to the public) to conduct two 6-month rounds of monitoring to determine whether or not the supply can be deemed optimal by definition or whether treatment must be installed. It did not anticipate a system serving

greater than 50,000 residents would disconnect from a regional supply to become its own supply with a new source and different treatment methods. It was these circumstances for which DEQ employees were sincerely applying regulations as they interpreted them to ensure compliance and public health protection.

Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan Safe Drinking Water Act (Act 399, PA 1976, as amended).

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (*check with Steve*), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated census that indicated the city's population had decreased to less than 100,000 (*check with Steve*). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

Why were some sample results submitted by the City of Flint during the latest monitoring period excluded from the 90th percentile compliance calculation?

Compliance samples must be ~~1-liter in volume and be~~ a first draw, 1 liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters,

etc. One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has point of use treatment (*check with Steve*). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

Although we already addressed the issue of why we did what we did in the first question after the "Issues around lead/copper," the following citation and explanation may be useful if needed to answer additional questions or ones we haven't yet asked:

Rule 325.l1064(f) (2) (D) (iii) says, "A water supply is considered to have optimized corrosion control if it submits results of tap water monitoring conducted under R 325.10710a and source water monitoring conducted under R 325.10710c that demonstrates, for 2 consecutive 6-month monitoring periods, that the difference between the ninetieth percentile tap water lead level computed under subrule (1)(c0) of the rule and the highest source water lead concentration is less than the practical quantification level (PQL) for lead. *(This is the procedure we were applying to Flint as they became a supplier and not just a consecutive system receiving finished water)* In addition, all of the following provisions apply:

(A) A supply whose highest source water lead level is below the method detection limit is considered to have optimized corrosion control under this paragraph if the supply's ninetieth percentile tap water lead level is less than or equal to the PQL for lead (which is 5 ppb) for 2 consecutive 6-month monitoring periods.

(B) A water supply considered to have optimized corrosion control under this paragraph shall continue monitoring for lead and copper at the tap not less frequently than once every 3 calendar years using the reduced number of sites specified in R 325.10710a(3) and collecting the samples at times and locations specified in R325.10710a(4)(d)(iv).

(C) A water supply is considered to have optimized corrosion control under this subdivision shall notify the department, in writing, under R325.10710d(a)(iii) of an upcoming long-term change in treatment or addition of a new source as described in that subdivision. The department shall review and approve the addition of a new source or long-term change in water treatment before it is implemented by the water supply. The department may require the supply to conduct additional monitoring or to take other action the department considers appropriate consistent with the requirements of R325.10604f(2) to ensure the supply maintains minimal levels of corrosion in the distribution system.

(D) & (E)……(lots more but not germane to the discussion)

Subparagraph (C) raises the issue of why Flint's change in source and treatment did not trigger additional department actions. One explanation has to do with whether the City of Flint was *"considered to have optimized corrosion control."* ODWMA staff did not consider Flint or any of the almost 300 other consecutive, customer water systems in Michigan that only receive and distribute finished water to be responsible for corrosion control treatment. It has been our practice to consider treatment of water to be the responsibility of the wholesale supplier, in this case DWSD. Therefore, this rule was not

considered applicable. Another explanation is that Flint already had authority to use the Flint River based on historic permits and periodic emergency use, so the city was not required to seek DEQ approval for a "new" source. And like every other large water system that initially came under the jurisdiction of the lead and copper rules, we were applying the overall procedure described in the above paragraph above subparagraphs (A) through (E) that allowed a system to demonstrate whether their current treatment methods were already deemed optimal. When the LCR was first implemented, numerous systems exceeded the lead action level of 15 ppb and wholesale suppliers had to optimize the corrosion control treatment. Under the regulatory framework allowed, some systems went 4 or more years before they had optimized their corrosion control, and in some cases, it took longer for it to take full effect in all of the consecutive customer supplies.

DRAFT

604f(2)(a) A supply shall complete the applicable corrosion control treatment requirements described in subrule (3) of this rule by the deadlines established in this rule. A large water supply (serving more than 50,000 persons) shall complete the corrosion control treatment steps specified in subdivision (d) of this subrule, unless the supply is considered to have optimized corrosion control under subdivision (b)(ii) or (iii) of this subrule. A small water system (serving 3,300 or fewer persons) and a medium size water system (serving more than 3,300, but fewer than 50,001 persons) shall complete the corrosion control treatment steps specified in subdivision (e) of this subrule unless the supply is considered to have optimized corrosion control under subdivision (b)(i), (ii), or (iii) of this subrule.	Applies because system >50,000.
604f(2)(b) A supply is considered to have optimized corrosion control and is not required to complete the applicable corrosion control treatment steps identified in subrule (3) of this rule if the supply is in compliance with 1 of the criteria specified in paragraphs (i) to (iii) of this subdivision. A supply which is considered to have optimized corrosion control under this subdivision and which has treatment in place shall continue to operate and maintain optimal corrosion control treatment and meet the requirements that the department determines appropriate to ensure optimal corrosion control treatment is maintained. All of the following provisions apply to being considered to have optimized corrosion control: (i) A small or medium size water supply is considered to have optimized corrosion control if the supply is in compliance with the lead and copper action levels during each of 2 consecutive 6-month monitoring periods during which monitoring is conducted under R 325.10710a. (ii) A water supply may be considered by the department to have optimized corrosion control treatment if the supply demonstrates, to the satisfaction of the department, that it has conducted activities equivalent to the corrosion control steps applicable to the system under subrule (3) of this rule. Supplies considered to have optimized corrosion control under this subdivision shall operate in compliance with the department designated optimal water quality control parameters under subrule (3)(g) of this rule and continue to conduct lead and copper tap and water quality parameter sampling under R 325.10710a(4)(c) and R 325.10710b(4), respectively. A supply shall provide the department with all of the following information to support a determination under this subdivision: (A) The results of all test samples collected for each of the water quality parameters specified in subrule	[redacted]: Treat as a new system or require system to maintain optimization because it was previously purchasing optimized water. EPA: Because the system had received optimized water, it was required to MAINTAIN that optimization. DEQ: While the system did previously receive the benefit of optimized water, it did not employ the optimization itself, so could not maintain what it did not have. Instead the new source/WTP were treated as a new, not yet optimized, system and required to begin optimization steps from the beginning.

(3)(c)(iii) of this rule.

(B) A report that explains the test methods used by the water supply to evaluate the corrosion control treatments listed in subrule (3) of this rule, the results of all tests conducted, and the basis for the supply's selection of optimal corrosion control treatment.

(C) A report that explains how corrosion control has been installed and how it is being maintained to ensure minimal lead and copper concentrations at consumers' taps.

(D) The results of tap water samples collected under R 325.10710a at least once every 6 months for 1 year after corrosion control has been installed.

(iii) A water supply is considered to have optimized corrosion control if it submits results of tap water monitoring conducted under R 325.10710a and source water monitoring conducted under R 325.10710c that demonstrates, for 2 consecutive 6-month monitoring periods, that the difference between the ninetieth percentile tap water lead level computed under subrule (1)(c) of this rule and the highest source water lead concentration is less than the practical quantitation level for lead. In addition, all of the following provisions apply:

(A) A supply whose highest source water lead level is below the method detection limit is considered to have optimized corrosion control under this paragraph if the supply's ninetieth percentile tap water lead level is less than or equal to the practical quantitation level for lead for 2 consecutive 6-month monitoring periods.

(B) A water supply considered to have optimized corrosion control under this paragraph shall continue monitoring for lead and copper at the tap not less frequently than once every 3 calendar years using the reduced number of sites specified in R 325.10710a(3) and collecting the samples at times and locations specified in R 325.10710a(4)(d)(iv).

(C) A water supply considered to have optimized corrosion control under this subdivision shall notify the department, in writing, under R 325.10710d(a)(iii) of an upcoming long-term change in treatment or addition of a new source as described in that subdivision. The department shall review and approve the addition of a new source or long-term change in water treatment before it is implemented by the water supply. The department may require the supply to conduct additional monitoring or to take other action the department considers appropriate consistent with the requirements of R 325.10604f(2) to ensure that the supply maintains minimal levels of corrosion in the distribution system.

(D) As of July 12, 2001, a supply is not considered to have optimized corrosion control under this subdivision, and shall implement corrosion control treatment under subparagraph (E) of this paragraph unless it meets the copper action level.

(E) A supply that is no longer considered to have

DEQ: Supplies can demonstrate optimization by meeting the PQL per 604f(2)(b)(iii). System was given this opportunity via 2 6-month rounds of standard tap monitoring.

EPA: When first round was 6 (not meeting PQL), why not begin study?

[redacted]: Why allow a 2nd 6-month round when first round did not meet PQL requirement?

next DEQ meeting

DEQ: DEQ was notified of the change. Because no prior tap monitoring data was available that represented the new source/WTP conditions, DEQ determined the appropriate action was to conduct additional monitoring to assess 604f(2)(b)(iii) applicability.

optimized corrosion control under this subdivision shall implement corrosion control treatment under the deadlines in subdivision (e) of this subrule. A large water supply shall adhere to the schedule specified in that subdivision for medium size water supplies, with the time periods for completing each step being triggered by the date the supply is no longer considered to have optimized corrosion control under this subdivision.	DEQ: Once monitoring demonstrated optimization could not be achieved by meeting the PQL requirement under 604f(2)(b)(iii), DEQ immediately notified the supply of the requirement to implement corrosion control treatment per 604f(2)(b)(iii)(E).
(c) If a small or medium size water supply exceeds the lead or copper action level and the supply is required to perform the corrosion control treatment steps, the supply may cease completing the treatment steps when the supply is in compliance with both action levels during each of 2 consecutive monitoring periods conducted under R 325.10710a and the supply submits the results to the department. If the supply thereafter exceeds the lead or copper action level during a monitoring period, the supply shall recommence the applicable treatment steps beginning with the first treatment step that was not previously completed in its entirety. The department may require a supply to repeat treatment steps that were previously completed by the supply if the department determines that this is necessary to properly implement the treatment requirements of this rule. The department shall notify the supply in writing of the determination and explain the basis of the decision. If a small or medium size water supply exceeds the lead or copper action level, the supply, including supplies considered to have optimized corrosion control under subdivision (b) of this subrule, shall implement corrosion control treatment steps under subdivision (e) of this subrule. (d) Except as provided in subdivision (b)(ii) and (iii) of this subrule, a large water supply shall complete all of the following corrosion control treatment steps by the indicated dates: (i) Step 1: A supply shall conduct initial monitoring during 2 consecutive 6-month monitoring periods by January 1, 1993. (ii) Step 2: A supply shall complete corrosion control studies by July 1, 1994. (iii) Step 3: By January 1, 1997, a supply shall install optimal corrosion control treatment as designated by the department. (iv) Step 4: A supply shall complete follow-up sampling by January 1, 1998. (v) Step 5: A supply shall operate in compliance with the department specified optimal water quality control parameters and continue to conduct tap sampling. (e) Except as provided in subdivision (b) of this subrule, small and medium size water supplies shall complete all of the following corrosion control treatment steps by the indicated time periods: (i) Step 1: A supply shall conduct initial tap sampling under R 325.10604f(3)(a) until the supply either	Corrosion control schedule for large systems found to no longer have OCCT.

exceeds the lead or copper action level or becomes eligible for reduced monitoring. The supply that exceeds the lead or copper action level shall recommend optimal corrosion control treatment within 6 months after the end of the monitoring period during which it exceeds 1 of the action levels. (ii) Step 2: Within 12 months after the end of the monitoring period during which a supply exceeds the lead or copper action level, the department may require the supply to perform corrosion control studies under subdivision (3)(b) of this rule. If the department does not require the supply to perform the studies, the department shall specify optimal corrosion control treatment under subdivision (3)(d) of this rule within the following timeframes: (A) For medium-size supplies, within 18 months after the end of the monitoring period during which the supply exceeds the lead or copper action level. (B) For small supplies, within 24 months after the end of the monitoring period during which the supply exceeds the lead or copper action level. (iii) Step 3: If the department requires a supply to perform corrosion control studies under subdivision (3)(b) of this rule, the supply shall complete the studies within 18 months after the department requires that the studies be conducted. If the supply has performed corrosion control studies under paragraph (ii) of this subdivision, the department shall designate optimal corrosion control treatment under subdivision (3)(d) of this rule within 6 months after completion of the corrosion control studies. (iv) Step 4: A supply shall install optimal corrosion control treatment within 24 months after the department designates the treatment. (v) Step 5: A supply shall complete follow-up sampling under R 325.10710a(4)(b) within 36 months after the department designates optimal corrosion control treatment. The department shall review the supply's installation of treatment and designate optimal water quality control parameters under R 325.10604f(3)(d)(ii) within 6 months after the supply's completion of follow-up sampling. (vi) Step 6: A supply shall operate in compliance with the department designated optimal water quality control parameters under R 325.10604f(3)(d)(ii) and continue to conduct tap sampling under R 325.10710a(4)(c) and R 325.10710b(6).	
(3) A water supply shall complete all the corrosion control treatment requirements described in this subrule that are applicable to the system under subrule (2) of this rule. All of the following apply: (a) Based on the results of lead and copper tap monitoring and water quality parameter monitoring, small and medium size water systems that exceed the lead or copper action level shall recommend the	This is what comes next. Completing the requirements, setting and maintaining ranges, etc.

DRAFT

installation of 1 or more of the corrosion control treatments listed in subdivision (c)(i) of this subrule that the supply believes constitutes optimal corrosion control for that system. The department may require the supply to conduct additional water quality parameter monitoring under R 325.10710b(4) to assist the department in reviewing the supply's recommendation.

(b) When required by the department, a small or medium size water supply that exceeds the lead or copper action level shall perform corrosion control studies under subdivision (c) of this subrule to identify optimal corrosion control treatment for the supply.

(c) Perform corrosion control studies as follows:

(i) A water supply that performs corrosion control studies shall evaluate the effectiveness of each of the following treatments and, if appropriate, combinations of the following treatments to identify the optimal corrosion control treatment for that supply:

(A) Alkalinity and pH adjustment.

(B) Calcium hardness adjustment.

(C) The addition of a phosphate or silicate based corrosion inhibitor at a concentration sufficient to maintain an effective residual concentration in all test tap samples.

(ii) The water supply shall evaluate each of the corrosion control treatments using pipe rig/loop tests, metal coupon tests, partial system tests, or analyses based on documented analogous treatments with other water supplies of similar size, water chemistry, and distribution system configuration.

(iii) A water supply shall measure all of the following water quality parameters in tests conducted under this paragraph before and after evaluating the corrosion control treatments listed in paragraph (i)(A) to (C) of this subdivision:

(A) Lead.

(B) Copper.

(C) pH.

(D) Alkalinity.

(E) Calcium.

(F) Conductivity.

(G) Orthophosphate, when an inhibitor containing a phosphate compound is used.

(H) Silicate, when an inhibitor containing a silicate compound is used.

(I) Water temperature.

(iv) The water supply shall identify all chemical or physical constraints that limit or prohibit the use of a particular corrosion control treatment and shall document the constraints with 1 or both of the following:

(A) Data and documentation demonstrating that a particular corrosion control treatment has adversely affected other water treatment processes when used by another water supply with comparable water quality characteristics.

(B) Data and documentation demonstrating that the

DRAFT

supply has previously attempted to evaluate a particular corrosion control treatment and has found that the treatment is ineffective or adversely affects other water quality treatment processes.

(v) A water supply shall evaluate the effect of the chemicals used for corrosion control treatment in other water quality treatment processes.

(vi) On the basis of an analysis of the data generated during each evaluation, a water supply shall recommend, to the department, in writing, the treatment option that the corrosion control studies indicate constitutes optimal corrosion control treatment for that supply. The water system shall provide a rationale for its recommendation together with all supporting documentation specified in paragraphs (i) to (v) of this subdivision.

(d) Department designation of optimal corrosion control treatment shall be as follows:

(i) Based on consideration of available information, including, where applicable, studies performed under subdivision (c) of this subrule and a supply's recommended treatment alternative, the department will either approve the corrosion control treatment option recommended by the supply or will designate alternative corrosion control treatment from the treatment specified in subdivision (c)(i) of this subrule. When designating optimal treatment, the department shall consider the effects that additional corrosion control treatment will have on water quality parameters and on other water quality treatment processes.

(ii) The department shall notify the supply of its decision on optimal corrosion control treatment in writing and explain the basis for this determination. If the department requests additional information to aid its review, the water supply shall provide the information.

(e) Each supply shall properly install and operate, throughout its distribution system, the optimal corrosion control treatment designated by the department.

(f) The department shall evaluate the results of all lead and copper tap samples and water quality control parameter samples submitted by the water supply and determine whether the supply has properly installed and operated the optimal corrosion control treatment designated by the department in subdivision (d) of this subrule. Upon reviewing the results of tap water and water quality control parameter monitoring by the supply, both before and after the supply installs optimal corrosion control treatment, the department shall designate all of the following:

(i) A minimum value or a range of values for pH measured at each entry point to the distribution system.

(ii) If a corrosion inhibitor is used, a minimum concentration or a range of concentrations for the inhibitor, measured at each entry point to the distribution system, that the department determines is necessary to form a passivating film on the interior walls of the pipes

DRAFT

of the distribution system.

(iii) If alkalinity is adjusted as part of optimal corrosion control treatment, a minimum concentration or a range of concentrations for alkalinity, measured at each entry point to the distribution system.

The department may designate values for additional water quality control parameters determined by the department to reflect optimal corrosion control for the supply. The department shall notify the supply in writing of these determinations and explain the basis for its decision.

(g) All supplies optimizing corrosion control shall continue to operate and maintain optimal corrosion control treatment, including maintaining water quality parameters at or above minimum values or within ranges designated by the department, under this subdivision for all samples collected under R 325.10710b(6) to (8). Compliance with the requirements of this subdivision shall be determined every 6 months, as specified under R 325.10710b(6). A water system is out of compliance with the requirements of this subdivision for a 6-month period if it has excursions for a department specified parameter on more than 9 days during the period. An excursion occurs when the daily value for 1 or more of the water quality parameters measured at a sampling location is below the minimum value or outside the range designated by the department. The department may delete results of obvious sampling errors from this calculation. Daily values are calculated as follows:

(i) On days when more than 1 measurement for the water quality parameter is collected at the sampling location, the daily value shall be the average of all results collected during the day regardless of whether they are collected through continuous monitoring, grab sampling, or a combination of both.

(ii) On days when only 1 measurement for the water quality parameter is collected at the sampling location, the daily value shall be the result of that measurement.

(iii) On days when a measurement is not collected for the water quality parameter at the sampling location, the daily value shall be the daily value calculated on the most recent day on which the water quality parameter was measured at the sample site.

(h) The department's determination of the optimal corrosion control treatment specified in subdivision (d) of this subrule or optimal water quality control parameters may be modified by the department. If a request for modification is by a supply or other interested person, the request shall be in writing, shall explain why the modification is appropriate, and shall provide supporting documentation. The department may modify its determination where it concludes that a change is necessary to ensure that the supply continues to optimize corrosion control treatment.

DRAFT

710a(3) = monitoring chart	Q: Why did DEQ allow 60 samples the 2nd round, rather than 100? A: System population was below 100,000. Per 710a(3), only 60 sites were required.
710a(1) = sample site locations	Q: Why did DEQ exclude sample results from the 90th percentile calculation? A: Sample sites are selected per 710a(1) using a tiered protocol designed to target high risk locations. Excluded results were taken at sites that did not meet site selection criteria.

DRAFT

Did DEQ review the information submitted by Flint to ensure all samples were from Tier I sites?

Yes. DEQ examined the information submitted and certified by the city that their LCR sampling pool consisted entirely of lead service lines from single family homes, which met the requirements of this rule to maximize sampling of high risk targeted sites.

During the initial implementation of the LCR approximately 25 years ago, water supplies were required to complete a materials evaluation of their distribution system to identify a pool of targeted, high-risk sampling sites. These sites were to be categorized into one of three tiers (I, II or III) based on risk. DEQ created a LCR reporting template for water systems to identify each compliance sampling site by Tier, and if they are in the highest Tier (1), to indicate why these sites qualify by having a lead service line, or because they either have copper piping installed with high lead content solder or they have lead plumbing in the home.

If a water system has sufficient Tier 1 sites, they are required to sample them before using any lower Tier sites. Furthermore, if they have sufficient sampling sites with lead service lines, they are required to use them to make up at least 50% of their sampling pool each monitoring period. Water supplies are also required to use the same sampling sites each time or explain on their LCR reporting form why they were unable to do so. Finally, we require the water system to certify all of the information they provide on the LCR reporting form is factual.

DEQ must rely upon the public water system to identify appropriate sampling sites for LCR monitoring. The DEQ public water supply program has no control or authority over service lines or domestic plumbing. As a result, we have no records on construction standards or materials used by customers for these components. If these records exist, they are kept locally where they are reviewed and approved by local agencies such as building departments or plumbing inspectors.

In 2015, Flint employees again certified that the information submitted on their LCR monitoring reports for the two 6-month rounds of monitoring conducted after they began treating the Flint River were accurate, and staff review of that information indicated it was in compliance with the monitoring requirements. It was not until October of 2015 when we heard city employees revealing to the media that they did not know for certain if their compliance monitoring was collected from homes with lead service lines. As a result, we began to investigate their monitoring sites. As the city began to transfer their customer information to electronic records, DEQ determined from the information available that a significant number of these sites that had been listed as having lead service lines either did not have them or ~~it was indeterminate~~. ~~At that point~~, DEQ notified the city in writing that it would be necessary to conduct a complete assessment of their sampling pool and report back their findings within a month. We are now awaiting the city's report.

the information was unavailable.

On November 2, 2015

City of Flint Drinking Water

Outline prepared by the

Michigan Department of Environmental Quality for the

Flint Water Task Force

I. Introduction

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act with respect to events in the City of Flint.

II. Background

1. How has Flint historically obtained its drinking water?

The water system in Flint, Michigan, was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally owned corporation which supplied drinking water to the City until 1967, ~~when~~ the City switched and become a customer of the Detroit Water and Sewerage Department (DWSD) system. After the switch to DWSD, the city of Flint operated their water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD was out of service for any reason.

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Michigan's Safe Drinking Water Act (1976 PA 399) and to keep mechanical equipment in good working order (such as valves, rubber seals, etc.) Each time the plant was test run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only ~~and~~ to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules must be complied with in order to ensure safe drinking water is provided to Flint residents?

The federal Safe Drinking Water Act (SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the SDWA, EPA sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (SDWA does not regulate private wells which serve fewer than 25 individuals.)

The federal SDWA authorizes the United States Environmental Protection Agency (US EPA) to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water. US EPA, states, and water systems then work together to make sure that these standards are met.

Originally, the SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to US EPA for "primacy," the authority to implement SDWA within their jurisdictions, if they can show that they will adopt standards at least as stringent as US EPA's and make sure water systems meet these standards. Michigan adopted the Safe Drinking Water Act in 1976 and maintained primacy for the program since 1978?

3. **What is EPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the Safe Drinking Water Act (SDWA), the U.S. Environmental Protection Agency (US EPA) is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards.

Michigan's drinking water program is reviewed annually by U.S. EPA.

4. **What is DEQ role's as a regulatory agency in implementing the SDWA?**

SDWA also allows states to accept oversight of the drinking water program under an agreement with US EPA giving states primary enforcement (or primacy) responsibilities. In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes.

The DEQ has primary enforcement authority in Michigan for the Safe Drinking Water Act under the legislative authority of the Michigan Safe Drinking Water Act (Act 399). As such, the division has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies.

The State of Michigan DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: visiting water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; providing financial assistance for system improvements; and conducting training sessions.

5. **What is Flint's role in implementing the SDWA?**

~~These federal and state programs are separate from the activities performed by water systems.~~ State and federal programs develop regulations and perform oversight and compliance activities, but do not actually treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers.

To ensure that drinking water is safe, SDWA sets up multiple barriers against pollution. These barriers include: source water protection, treatment, distribution system integrity, and public information. As a public water system, the city of Flint is responsible for ensuring that contaminants in tap water do not exceed the standards. The City treats the water, and must test their water frequently for specified contaminants and report the results to the State. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The SDWA recognizes that since everyone drinks water, everyone has the right to know what's in it and where it comes from. The City of Flint, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports on the source and quality of their tap water.

The city of Flint submits samples of their water for laboratory testing (monitoring) to verify ~~that~~ the water they provide to residents meets all federal and state standards. How often and where samples are taken varies from system to system and contaminant to contaminant. The State provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the city of Flint is required to maintain on staff, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the city's water system.

III. **The Flint River – it is a safe source of drinking water?**

In Michigan, we are blessed with high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, most with intakes in the Great Lakes. A handful of public water supplies in Michigan do treat water from inland sources such as rivers or groundwater under the influence of surface water. While river sources present a greater challenge for

[Our impression is that the average citizen is under the impression that the river water is corrosive and contains lead – we can address no lead, chloride, and lime issues. Address treatment issues to show that water leaving the plant meet all SDWA

requirements. Ph was same as DWSD. Also sets up point that problems arose after water left plant and was disseminated throughout system]

IV. E. Coli and Total Coliform bacteria violations

1. What caused the E.Coli and Total Coliform bacteria violations experienced by Flint in August-September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWA's) in the City of Flint during August and September 2014. While use of the Flint River increased the amount of natural organic matter in the City's water, the City's water treatment plant (WTP) performed well above treatment requirements for organic carbon removal. In addition, less than 20% of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the City, rather than in such a localized area.

The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses and industrial property. Declining water use leads to excess ~~residence~~ time within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30%, saw even greater losses since February due to an increase in cold weather related water main breaks and leaks. The City lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWA were found to be closed during the City's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure.

The BWA's also occurred during the warmest and ~~for 2014~~ relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were many broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected and what was DEQ's response?

The Boil Water Advisories (BWAs) which occurred in the City of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City of Flint collaboratively in consultation with the DEQ.

Regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the EPA, have been in effect since 1990, and incorporated into the Michigan Safe Drinking Water Act. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for Total coliform and E.coli. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system ~~minimizes the~~ likelihood that pathogens are present. E.Coli is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for ~~a period of~~ 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

A BWA was issued from August 15–20, 2014, for a portion of the City of Flint due to localized detections of total coliform and E.Coli bacteria. Another BWA was issued from September 5-9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City of Flint. The advisory covered an area approximately 6 square miles. The City of Flint has a total land area just over 34 square miles.

V. TTHM violations

1. What caused the TTHM violations experienced by Flint beginning in late Summer 2014?

TTHMs and HAA5s are the result of organic material in the water reacting with disinfectant used to treat the water. The Flint River has higher levels of organic material than water in the Great Lakes and ~~it was not a surprise that~~ the water produced by the city of Flint developed higher disinfection by-products than the water provided by DWSD. However, because the water treatment plant was previously operating intermittently as an emergency backup supply, it was not possible to predict disinfection byproduct formation until the city began relying on it continuously.

2. How were the violations detected and what was DEQ's response?

In ~~preparation~~ to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't actually violate the safe drinking water act standard until the fall, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, the city was asked to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on September 1, 2015.

IV. The taste, odor, and smell complaints received by Flint

1. What caused the taste and odor complaints received by Flint from residents?

Taste and odor issues are very personalized. Some water systems receive complaints because of too much disinfectant. In Flint, during the summer after the switch to the Flint River as a water source, taste and odor complaints increased. It was believed at the time to be the result of changes in hydraulic conditions within the distribution system. Water leaving the water treatment plant did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing and changes in flow characteristics are all know causes of disturbances with the distribution system that can cause an increase in taste and odor complaints.

2. What was DEQ's response?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) ~~can and will~~ cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

V. The lead issues in the Flint drinking water

1. What causes lead in drinking water?

Lead is rarely found in source water, but enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead pipes, fixtures and solder. The most common problem is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. Lead can leach into water from pipes, solder, fixtures and faucets (brass), and fittings. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What are the lead action levels?

For most contaminants, EPA sets an enforceable regulation called a maximum contaminant level (MCL) based on the MCLG. MCLs are set as close to the MCLGs as possible, considering cost, benefits and the ability of public water systems to detect and remove contaminants using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, EPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to ensure control of a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper rule) requires water systems to control the corrosivity of the water. The regulation also requires systems to collect tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10% of tap water samples exceed the lead action level of 15 parts per billion, then water systems are required to take additional actions including:

•Taking further steps optimize their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control) .

•Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

•Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

3. Are there any safe levels of lead?

The SDWA requires EPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLG) The MCLG for lead is zero. EPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

4. What is the LCR?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, EPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 ppm in more than 10% of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the action level for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

5. Did DWSD have a corrosion control plan?

After the LCR ~~was~~ passed, DWSD conducted two rounds of monitoring at for lead and copper. Copper levels were well below action level limits; but lead levels exceeded the action level of 15 parts per billion in many of their customer communities. As a result, DWSD needed to install corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an ortho-phosphate.

6. Did DEQ require Flint to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. The DEQ believed ~~there were two ways~~ under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to ~~call~~ for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were

initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

7. How does DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the following steps are followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Multiples of 10 require no averaging or interpolation.

8. What was the result of the first round of monitoring conducted by Flint?

The first 6-month round of lead and copper monitoring conducted by the city of Flint ended on December 31, 2014. One hundred samples ~~100 samples~~ were submitted and the 90th percentile lead level was calculated to be 6 parts per billion.

A 90th percentile lead result of 6 ppb is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the city of Flint ended on June 30, 2015. Sixty nine samples were submitted and the 90th percentile lead level was calculated to be 11 parts per billion. The conclusion from these results was that the city exceeded the level required to be deemed as having optimized corrosion control but did not exceed the action level of 15 parts per billion.

10. What actions did DEQ order Flint to undertake after the second round of monitoring?

While the City's LCR compliance monitoring continued to meet action level requirements, the LCR requires all large systems (those serving over 50,000 people) to optimize corrosion control regardless of their 90th percentile lead concentration. Following receipt of Flint's compliance monitoring results, the DEQ required the city to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the city has 6 months to let the DEQ know whether it intends to conduct a study, 18 months to perform the study, and 24 months to complete installation of corrosion control. The DEQ has requested the city of Flint to accelerate this schedule. The city submitted plans and specifications to install corrosion control treatment and a construction

permit was issued by DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November.

11. What had DHHS advised DEQ regarding blood lead levels prior to DEQ ordering Flint to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.
- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

Insert GRAPHS?

This e-mail in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City of Flint had not exceeded an action level for lead provided the basis for DEQ to maintain that the water in Flint continued to be in compliance with the SDWA and was safe for consumption.

12. When did DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015 by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by U.S. EPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August.

By this time, the City of Flint had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment in

[Hurley and Edwards all after the fact]

VI. Questions raised regarding DEQ's actions

1. What was DEQ's response to EPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by Flint under the LCR?

DEQ indicated that the city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether or not second round of monitoring which would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

2. Did DEQ attempt to mislead EPA in a February 27, 2015 email responding to EPA's inquiry regarding OCCT?

No. There is an e-mail from Steve Busch indicating that the city was practicing corrosion control. This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

3. Has EPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by DEQ?

to all 20 states

On November 3, 2015, U.S. EPA issued a Memorandum regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The memo states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take/apply in the future.

4. Did DEQ reject any of the samples submitted by Flint?

According to the LCR,

Yes, samples at two locations were excluded from the compliance calculation.

Compliance samples must be a first draw, 1 liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc. One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has whole house treatment system (check with Steve). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

5. **Did DEQ review the information submitted by Flint to ensure all samples were from Tier 1 sites?**

6. **Did DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. Subsequent sampling taken at this address showed that replacement of the service line mitigated the problem. There was also no reason to believe that this was indicative of a system-wide problem.

7. **Do DEQ's sampling instructions comply with the LCR?**

8. **Does DEQ require the use of small-neck bottles to obtain samples?**

9. **Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?**

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan SDWA.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

couldn't have been an updated census prior – maybe a census projection?

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (check with Steve), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated census that indicated the city's population had decreased to less than 100,000 (check with Steve). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

10. Why did DEQ admit it made a mistake?

information

I. The Flint River – is it a safe source of drinking water?

In Michigan, we are fortunate to have high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, the majority of which is withdrawn from the Great Lakes. A handful of public water supplies in Michigan do treat water from inland rivers, lakes or groundwater under the influence of surface water. All surface water sources and groundwater under the influence of surface water requires significant treatment in order to be safe for consumption. Treatment of surface water is referred to under Act 399 as "complete treatment".

While all surface water sources must receive this higher level of treatment, river sources present a greater challenge than water withdrawn from one of the Great Lakes. River sources are more challenging to treat because of how rapidly water quality may change compared to Great Lakes Sources. Under most circumstances, rivers are also prone to greater fluctuations in temperature, have higher amounts of organic material, greater turbidity (suspended solids), and are more vulnerable to microbiological and viral contamination than Lakes Huron, Erie, Michigan or Superior. It should be noted, that while the water chemistry in the Flint River differs from that in Lake Huron, it can still be treated in accordance with the SDWA and Act 399. Many cities across the country rely on similar sources for drinking water. The waterworks industry has the technology to treat wide ranging source waters to provide potable and palatable drinking water, including direct reuse of wastewater. Regardless of source water quality, all public water systems must comply with the same drinking water standards in the finished water.

Also, it is not the source water that reacts with the homeowners plumbing out in the distribution system, but rather the finished water quality that is important. To begin with, neither the Flint River nor the treated water leaving the City of Flint's water treatment plant contains lead. In addition, the treatment process employed by the City of Flint includes lime softening to reduce the hardness in the river water. Lime softening is not a process that would typically be thought to increase corrosivity of water. The City of Flint, however, does practice recarbonation to readjust pH at the end of the softening process. pH levels of finished water leaving the City of Flint's water treatment plant averaged 7.7. Water monitoring conducted quarterly at 25 sample sites located throughout the distribution system showed the following:

July – September 2014	average pH = 7.71	range: 7.56 – 7.86
October – December 2014	average pH = 7.88	range: 7.62 – 8.10
January – March 2015	average pH = 7.81	range: 7.60 – 7.99
April – June 2015	average pH = 7.63	range: 7.48 – 7.80

The following data was obtained at the same sampling locations throughout the city of Flint's distribution system, but while they were still purchasing water from DWSD before Flint switched to the River as a source:

January – March 2014 (DWSD)	average pH = 7.47	range: 7.40 – 7.54
April 2014 (DWSD)	average pH = 7.49	range: 7.42 – 7.59

Note that the pH numbers while the city was treating the Flint River did not differ significantly from those produced by DWSD, and in fact tended to be slightly higher (less corrosive).

1. **When did DEQ first become aware of allegations of elevated blood levels being detected in certain children?**

The DEQ was notified on August 23, 2015 by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by U.S. EPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August. In early September, information was reported in news articles that pediatricians in the City of Flint had data suggesting an increase in children's blood lead levels in two zip codes in the Flint area.

By this time, the City of Flint had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment as documented in correspondence dated August 17, 2015.

1. **Did DEQ review the information submitted by Flint to ensure all samples were from Tier 1 sites?**

2. **Do DEQ's sampling instructions comply with the LCR?**

We continue to disagree with EPA on sampling protocols. We have attempted to ensure compliance with EPA guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, we had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was EPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in compliance calculations.

Subsequently, EPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, we devised our current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

We continue to believe it is appropriate to flush these taps the day before sample collection to simulate and/or ensure typical household use before the tap is allowed to sit overnight to achieve the expected stagnation time the regulation recommends a minimum 6 hours stagnation prior to collecting the first draw sample. The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. Until EPA changes this rule, we are satisfied with our sampling protocol.

3. Does DEQ require the use of small-neck bottles to obtain samples?

No. The DEQ does not mandate the use of small-neck bottles; it is the sampling method that is specified in both the SDWA and Act 399. Each certified drinking water laboratory provides bottles to their customers upon request for any particular analysis. The bottles provided by the DEQ Drinking Water Laboratory for a lead and copper corrosion control sample do happen to have a small cap opening.

4. Why did DEQ admit it made a mistake?

Why did DEQ Admit mistakes and Apologize?

~~Why did the DEQ Apologize?~~

The mounting FOIAs brought to the Director's attention information from within the department that was not previously known to the Director – specifically, that EPA field staff had raised the question of corrosion control in the Spring of 2015 and had been critical of the Department's protocol and testing process. It seemed clear that the EPA field staff had opined that DEQ staff had employed the incorrect protocol. In the face of that new information, the DEQ Executive felt compelled to acknowledge that an error may have been made as part of moving the conversation and the situation forward.

The subsequent acknowledgement by EPA's regional and headquarters leadership that the Lead and Copper rule speaks ambiguously on the issue of continued corrosion control, and that the DEQ did not employ a protocol that was 'wrong,' was of considerable consolation to department staff but only left agency leadership feeling more resolute that the rule needs to be changed, and the Michigan DEQ is interested in being part of that process.

Also, There should not have been any disrespect or discredit for those who Raised ~~the~~ the lead in water issue in Flint. For a time that did not Recognize the Seriousness of the issue, the Director did Apologize.

City of Flint Water
Action Steps for Week of October 26-30

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	Initial meeting held 10/22/15
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
3.	After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A meeting with the 10 remaining schools is tentatively scheduled for the week of 10/26/15
7.	Meet with DHHS and discuss all lead education material for schools	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting
8.	Review corrosion control treatment plan and get any EPA comments	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Summary of Flint's corrosion control plan submitted to EPA
9.	Review construction permit application and issue construction permit for phosphate equipment	DEQ	Jim Sygo Steve Busch Pat Cook	Additional discussions are in progress with city of Flint

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
			Mike Prysby	
10.	Review Standby Operation of Flint Water Treatment Plant with city of Flint	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Comments by DEQ to city of Flint have been provided
11.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues. Check weekly for status update.	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Issues regarding soil erosion controls during construction are being addressed
12.	Contact city of Flint for Service Line Record status update and obtain a copy of the records to date	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	
13.	Provide DHHS with any available cross-reference information	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
14.	Develop childcare facility guidance or review DHHS related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting
15.	Create a generic school sampling guidance document for statewide distribution. Target audience: schools served by municipal water.	DEQ and LARA	Jim Sygo Steve Busch Richard Benzie	
16.	Confirm plumbing assessment and sampling is scheduled for Brownell K-2 STEM Academy and Eisenhower Elementary.	DEQ and LARA	Jim Sygo Steve Busch Mike Prysby	

City of Flint Water
Action Steps for Week of November 9-13

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	Meeting held on 10/29/15 to discuss time line
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
3.	Assist After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	Negotiations underway to contract with the Genesee County Health Department
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A summary report for Freeman Elementary School has been drafted
7.	Follow up with city of Flint regarding corrosion control treatment and their plans to address requirements and options provided for in 10/30/15 DEQ letter	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
8.	Follow-up with city of Flint regarding installation of corrosion control	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	E-mailed city of Flint on 11/4/15; 11/5/15 response indicated equipment to be ordered and plan to start installing feed piping on 11/9/15
9.	Review Monthly Operation Reports (MORs) for Standby Operation of Flint Water Treatment Plant with city of Flint; draft letter to city of Flint documenting Standby Operation requirements	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Letter is drafted and will be sent to city of Flint the week of 11/9/15; MOR review with city of Flint will be conducted during next routine site visit
10.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues; check weekly for status update	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Issues regarding soil erosion controls during construction are being addressed
11.	Continue evaluating city of Flint Service Line Record status and comparison to sampling pool	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Letter requesting additional information/documentation to be provided to city of Flint on 11/9/15
12.	Provide DHHS with any available cross-reference information regarding lead service lines and plumbing materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
13.	Develop draft sampling protocol for residential exposure assessment for DHHS	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Draft document under development; discussed preliminary plan with DHHS

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
14.	Make progress on drafting a generic school sampling guidance document for statewide distribution; target audience: schools served by municipal water	DEQ and LARA	Jim Sygo Steve Busch Richard Benzie	Draft document under development to make it an easy-to-read and follow guidance document
15.	Attend Technical Advisory Committee meeting on November 9, 2015	DEQ	Jim Sygo Mike Prysby	
16.	Draft Summary Reports for Brownell Elementary and Eisenhower Elementary	DEQ and LARA	George Krisztian Steve Busch	
17.	Conduct Plumbing Assessments at Durant-Tuuri-Mott Elementary and Central Kitchen	DEQ and LARA	George Krisztian Steve Busch	
18.	Conduct Sampling at Durant-Tuuri-Mott Elementary and Central Kitchen	DEQ and LARA	Jim Sygo George Krisztian Mike Prysby	
19.	Evaluate Lab Analysis and Perform Data Compilation for Doyle Ryder Elementary and Pierce Elementary	DEQ	George Krisztian Steve Busch Mike Prysby

Harvey,
We've got two issues I wanted to update you on. After trying to do this all in a single email, I realized it gets messy. So this is the first of two.

The water quality question remains under consideration. I've had a couple meetings this week with our drinking water team. I will circle back and push them for a specific recommendation on a good retail filter. Thus far, they've presented a range of options and been uncomfortable going past that because a) we don't specialize in home filtration. We're in charge of commercial / municipal size systems. And b) most filtration systems remove contaminants and toxics and organics. There's no way to know for sure if a faucet model will effectively work on odor or color issues until someone installs it and tries it out. For that, we'd need a home that has reported discolored / smelly water. And for that, I'd imagine we'd need to connect with the city and see if they've got logs of residents who have made these complaints.

The other potential help that could come from the state – and after conversations with our folks I maintain it might be the best help we can give them – has to do with maintenance. Of the $2 million announced in January from Treasury, $900,000 was earmarked for developing a maintenance triage plan. As that comes together, the next step will be actual maintenance. This means replacing valves and rotten sections of pipe, but it also means "pigging" lines with an inline device that runs through water transmission lines and forces out any built-up… material. In coordination with bleeding stagnant water via hydrants, this would probably be the fastest, most effective way to address the discolored / odorific water.

Our department specialists working with Flint imparted in an internal meeting this morning that the city has been a little reticent to pig their lines because the system is in such a condition that they worry a valve opened won't close (and vice versa), and a line that is barely still functional might get blown by the pigging. Our position is that would be preferable – maintenance, after all, is about addressing those very situations. But if funding can be identified, through SOM or some foundation benefactor,

and we can convince the city to tackle the work, this would be a great way to spend it. The PDF files enclosed offer some more information about what this is, how it works, etc.

I'm still working to get a report of all the local municipal violations over the past two years. The two staff in the drinking water division who run those database searches are out of state this week, in Florida and Alaska respectively. Division assures me they'll get that report run as a priority upon return of those folks next week. In the meantime, here are some images (the Jpeg titled COLLAGE). It shows various conditions, mostly at mobile home parks around the state, where the water system has failed. May or may not be of use, but if nothing else it exemplifies that this stuff happens, much as we try to make sure it does not.

This is email one of two. The other issue I will present in the next email. If it is at all possible, I'd suggest we need to assemble Treasury, MDCH, DEQ and Ambrose + RS team sometime Monday to get everyone briefed on what each agency is doing in Flint right now and what we may need to do next. Don't know if that meeting gets called by you or Dennis, but I think you and I agree that we need a united, coordinated team approach to develop quickly.

Thanks,
b

Office of Mayor Karen W. Weaver, Ph.D.
City of Flint, Michigan, County of Genesee

Declaration of State of Emergency

Authority Emergency Management Act: Michigan Emergency Management Act 390 of 1976

BY THE MAYOR:

Whereas; in accordance with the Michigan Emergency Management Act, I am declaring a State of Emergency for the incorporated boundaries of the City of Flint, Michigan; and

Whereas; the City of Flint has experienced a Manmade disaster by switching to the use of the Flint River before connecting to KWA; and

Whereas; the City of Flint children have experienced increased blood lead levels since the switch to the Flint River; and

Whereas; this damage to children is irreversible and can cause effects to a child's IQ, which will result in learning disabilities and the need for special education and mental health services and an increase in the juvenile justice system; and

Whereas; this will increase the need for foster and adoptive parents as a result of social services needed due to the detrimental effects of the high blood lead levels; and

Whereas; I am requesting that all things be done necessary to address this State of Emergency Declaration, effective immediately; and

Whereas; this action is being taken to protect the health, safety, and welfare of the citizens of Flint; and

Whereas; I request that the Genesee County Board of Commissioners call a Special Meeting no later than the end of December 2015 to take action supporting this State of Emergency; and

Now, Therefore, I, Mayor Karen W. Weaver declare a State of Emergency in the City of Flint, effective, December 14, 2015;

Karen W. Weaver

Dr. Karen W. Weaver, Mayor

Subject: Part II
Attachments: FOIA Request Flint Water.doc

Importance: High

This is the second issue I mentioned earlier today.
In December, our staff became peripherally aware that the hospitals in Genesee were seeing an uptick in Legionnaires cases.

Legionnaires is a water-borne illness. It essentially is a type of pneumonia caused by a bacteria. It is treated with antibiotics. Untreated, it can be deadly. It most often manifests in nursing homes and assisted living facilities, because the transmission is through water vapor getting into lungs – via air conditioners, vaporizers or low-flow shower heads that produce a lot of misting. You can drink water with this bacteria in it and not get sick – it has to enter the lungs in vapor.

I don't have any details on the cases, but here is what I understand to this point:

- More than 40 cases reported since last April. That's a significant uptick – more than all the cases in the last five years or more combined.
- April / May is usually the start of Legionnaires season – it proliferates in warmer months – but April also is the point at which the city switched to the Flint River as a source.
- County Health Departments are supposed to perform epidemiological tracebacks on all confirmed cases of this disease, to locate the source and address it. Genesee County Health had not done this work as of November. At a January meeting with area hospitals, MDCH, DEQ and others, Nick Lyon reportedly directed the county health folks, in terms not uncertain, to get this done as a priority. As I'm sitting here today, it still is not done to my knowledge.
- My counterparts at MDCH informed me today that they cannot step in unless they are invited or unless the outbreak is multi-county. They've not been invited until, I believe, today. That may be in part because of the email string and letter I've enclosed here, which was unknown to MDCH until I shared it over to them.

The email thread below is best read bottom-to-top, and read prior to reading the enclosed FOIA to the city.

Essentially, Jim Henry with Genesee County Health is putting up the flare. He's made the leap formally in his email that the uptick in cases is directly attributable to the river as a drinking water source – this is beyond irresponsible, given that is his department that has failed to do the necessary traceback work to provide any conclusive evidence of where the outbreak is sourced, and it also flies in the face of the very thing a drinking water system is designed to do.

DEQ did not receive this FOIA, which appears designed to buttress his position in the email -- that sections of the water delivery system may be harboring this bacteria. We think it would be highly unlikely that anything would be found around the plant, where the water is treated. Most often, this bacteria forms at the building / residential point in the system. Legionnaires is NOT among the 90 water contaminants screened in the Safe Drinking Water Act, but in the absence of action by county health, our staff are now considering taking samples from various points in the system and working with DCH's lab to test for it, if for no other reason than to rule it out.

Regardless, the accusation is serious and the nature of the communication leaves me thinking we would be advantaged to bring together all the agencies asap to share what information we have and develop a response / screening strategy before the weather gets warm again.

I realize these are long emails. Thanks for your patience.

Importance: High

The district received this late Tuesday.

Steve Busch has indicated that the district has not received a meeting request from Jim Henry or the Genesee County Health Department as indicated in his email below.

The FOIA is specifically directed to the City of Flint not the DEQ.

While the change in source may have created water quality conditions that could provide additional organic nutrient source to support legionella growth, there is no evidence or confirmation of legionella coming directly from the Water Treatment Plant or in the community water supply distribution system at this time.

Seems like the next step is to communicate with DCH and possibly develop a joint strategy/response. Not sure who in Exec wants to take the lead on this. Steve Busch and Mike Prysby will continue to be lead for us on this. They have been in contact with DCH recently but only to learn that little progress has been made in identifying a source or sources for the illnesses.

EMAIL FROM DEQ TO HENRY SENT THIS AFTERNOON:

Mr. Henry,

The January 27, 2015, FOIA request you provided was directed to the City of Flint, not the DEQ. The DEQ has no record of a FOIA request from your office for such information. It is our understanding that the City has responded to your FOIA request, has helped you adequately redefine your request within the City's scope of public record to address such ambiguities as "any additional areas of concern", and provided you with additional information beyond the scope of your request.

The DEQ fully recognizes the public health threat posed to individuals that contract Legionnaires' Disease with the understanding that the disease is not contracted by ingestion of potable water and therefore not regulated under the federal Safe Drinking Water Act. Your email below claims that you have explicitly explained the situation to our Department. However, since contacting our office early last October to indicate a rise in cases, we have not received any further information regarding your epidemiological investigation into this matter.

Further, conclusions that legionella is coming from the public water system without the presentation of any substantiating evidence from your epidemiologic investigation appears premature and prejudice toward that end.

It is highly unlikely that legionella would be present in treated water coming from the City of Flint water treatment plant given the treatment plant's use of ozone along with complete treatment and chlorine disinfect contact time to comply with federal surface water treatment rules for potable water. Detections of total coliform or heterotrophic bacteria in the City's public water distribution system indicate an environment where bacterial growth may be supported. However, there is no direct correlation that can be made to the presence of legionella. While total organic carbon levels in potable water may serve as a food source for bacteria growth in private plumbing system, water temperatures in the City's distribution system are below legionella growth range, and chlorine residual levels would also limit such growth.

Our office agrees that water main breaks, water leaks, and system repairs are possible vectors for legionella to enter the public water system. These should be investigated as part of your epidemiology. DEQ staff can be made available to assist GCHD and the City regarding such matters, but to date no request by GCHD for any such meeting has been received, let alone declined as alleged in your email.

If GCHD is seeking assistance to complete its epidemiological investigation regarding this matter, such resource requests should be directed to the Michigan Department of Community Health. Our Office agrees that a multi-agency partnership would be beneficial to move forward and develop a unified response. In that respect, if our Office can be of any further assistance you may contact me directly.

Stephen Busch, P.E.
Lansing and Jackson District Supervisor
Office of Drinking Water and Municipal Assistance

Subject: Information Request and Documentation

Hello everyone,

The Genesee County Health Department has made several written and verbal requests for specific information since October, 2014, including a Freedom of Information Act Request on January 27, 2015. The information still has not been received and the city's lack of cooperation continues to prevent my office from performing our responsibilities.

The Genesee County Health Department has the responsibility to conduct illness investigations and consider all potential sources; this is not optional. In 2014, Genesee County experienced a significant increase of confirmed Legionella illnesses relative to previous years. Legionella can be a deadly, waterborne disease that typically affects the respiratory system.

The increase of the illnesses closely corresponds with the timeframe of the switch to Flint River water. The majority of the cases reside or have an association with the city. Also, McLaren Hospital identified and mitigated Legionella in their water system. This is rather glaring information and it needs to be looked into now, prior to the warmer summer months when Legionella is at its peak and we are potentially faced with a crisis.

This situation has been explicitly explained to MDEQ and many of the city's officials. I want to make sure, in writing that there are no misunderstandings regarding this significant and urgent public health issue. The Trihalomethane issues "pale in comparison" to the potential public health risks of Legionella.

I am submitting the attached FOIA request again and requesting that the legal obligations of the request are met. If the information is not available, please let me know. In the past, I have requested to meet with the water plant staff and MDEQ regarding Legionella concerns. I did not receive a response from the water plant staff and MDEQ declined. I think it is in the best interest for all stakeholders that we meet and discuss the issues.

Respectfully,

Jim

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

April 29, 2014

Mr. Daugherty Johnson, Utilities Administrator
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502

WSSN: 02310

Dear: Mr. Johnson

Subject: Act 399 Capacity and Reliability Requirements

This letter, per your request, is being written as verification that the City of Flint water system is currently in compliance with required capacity and power service reliability requirements under the Michigan Safe Drinking Water Act and Administrative Rules, Supplying Water to the Public.

The required capacity of a waterworks system as established in Rule 1204 (R 325.11204) required sufficient capacity to meet approved finished water supply requirements, and is based upon the combination of the following options:

a. Rated capacity of an approved surface water supply or complete treatment system;
b. Firm capacity of approved groundwater supply;
c. Available contracted capacity that can be delivered from another public water supply;
d. Excess finished water storage capacity.

Under the first option listed above, the City's baseline water withdrawal capacity from the Flint River, and rated capacity of the City's water treatment plant (WTP), both exceed its finished water supply requirements. The rated capacity of a complete treatment system is established under Rule 1006 (R 325.11006). In accordance with this rule, the Department of Environmental Quality (DEQ) has established a rated capacity of 36 million gallons per day for the City's WTP, which again far exceeds current and future finished water supply requirements for the City's service area.

In addition, while capacity under item d above for excess finished water storage has not been established, the City currently has enough finished water storage to supply more than 2 days of normal finished water supply requirements

Rule 1206 (R 325.11206) requires water systems to provide a means to continuously supply fully finished water during normal power service interruption. The City's WTP is now equipped with a redundant electrical system that includes provisions for stand-by power generation; thus meeting this requirement.

While additional means to meet the above requirements for capacity and power interruption can be provided through contracted interconnections with other water systems, the City has demonstrated compliance with these requirements without such means. However, the DEQ still supports and encourages such interconnections be maintained for emergency purposes as an additional barrier to help maintain public health protections. While these emergency

interconnections have no requirement to establish an available or contracted capacity, the DEQ encourages the corresponding utilities to establish mutual aid agreements where possible. Such agreements can be developed through the Michigan Water/Wastewater Agency Response Network (MiWARN). For more information, please visit miwarn.org. A MiWARN brochure is also enclosed for your information.

If you have any questions, feel free to contact me at (517) 290-8817; prysbym@michigan.gov; or Department of Environmental Quality, Office of Drinking Water and Municipal Assistance, Lansing District Office, 525 West Allegan Street, 1st Floor South, P.O. Box 30242, Lansing, Michigan 48909-7742.

Sincerely,

Michael F. Prysby, P.E.

STATE OF MICHIGAN
EXECUTIVE OFFICE
LANSING

RICK SNYDER
GOVERNOR

BRIAN CALLEY
LT. GOVERNOR

PROCLAMATION

DECLARATION OF EMERGENCY

WHEREAS, Section 1 of Article V of the Michigan Constitution of 1963 vests the executive power of the state of Michigan in the Governor; and

WHEREAS, under the Emergency Management Act, Act No. 390 of the Public Acts of 1976, as amended, MCL 30.401 to 30.421, the Governor is responsible for coping with dangers to this state or the people of this state presented by a disaster or emergency or threat thereof, and may issue executive orders and proclamations, having the force and effect of law to implement the Act; and

WHEREAS, under Section 3 of the Emergency Management Act, 1976 Public Act 390, MCL 30.403, the Governor shall, by executive order or proclamation, declare a state of emergency if the Governor finds that an emergency has occurred or that the threat of an emergency exists; and

WHEREAS, on April 25, 2014 the City of Flint, Michigan switched from the Detroit water system to the Flint River as a water source, the harmful effects of untreated water struck the city's water infrastructure, causing leaching of lead into the water which caused damage to the water system and potential negative health impacts to the citizens; and

WHEREAS, the area affected includes parts of the City of Flint, within the County of Genesee; and

WHEREAS, the damaged water infrastructure and leaching of lead into the city's water caused damage to public and private water infrastructure, and has either caused or threatened to cause elevated blood lead levels, especially in the population of children and pregnant women, and causing a potential immediate threat to public health and safety and disrupting vital community services; and

WHEREAS, from October 1, 2015 to this date, the County of Genesee and the City of Flint have taken a number of actions to cope with the situation, including but not limited to, switching back to the Detroit water system on October 16th, declaring local states of emergency, activating the emergency response and recovery aspects of their emergency operations plan, marshaling

and distributing required resources on a city-wide level, and issuing emergency public information and bulletins; and

WHEREAS, local resources have been insufficient to address the situation, and additional assistance from voluntary organizations and the state is required to protect public health, safety, and property, and to lessen or avert the threat of more severe and long lasting impacts to the community;

NOW, THEREFORE, I, RICHARD D. SNYDER, Governor of the state of Michigan, pursuant to the Constitution of the state of Michigan and provisions of Act No. 390 of the Public Acts of 1976, as amended, do hereby proclaim that a state of emergency exists in the aforementioned county and municipality; and

FURTHER, the Emergency Management and Homeland Security Division of the Department of State Police shall coordinate and maximize all state efforts, and may call upon all state departments to utilize resources at their avail to assist in the emergency area pursuant to the Michigan Emergency Management Plan; and

FURTHER, termination of this emergency will occur at such time as the threats to public health, safety, and property caused by the emergency no longer exist and appropriate programs have been implemented to recover from the effects of this emergency, but in no case longer than February 1, 2016, unless extended as provided by Act No. 390.

Given under my hand and the
Great Seal of the State of Michigan this
5th day of January in the Year of Our
Lord, Two Thousand and Sixteen.

RICHARD D. SNYDER
GOVERNOR

BY THE GOVERNOR:

SECRETARY OF STATE

FILED WITH SECRETARY OF STATE
ON 1/5/16 AT 4:00pm

City of Flint
Technical Advisory Committee - Weekly Report

October 28th, 2015

Last meeting: 10-7-2015
Next meeting: 11-18-2015, 2:00 pm

I. Overview –

Please note that we have set the date for the next meeting at **Wednesday November 18th** 2:00 pm at Flint City Hall (there will be a call in number). The previous date proposed is Veterans Day and there were several conflicts.

II. New Items this week

Technical Advisory Committee Addition

I have added Professor Shawn McElmurry, An Associate Professor at Wayne State University in the Dept. of Civil and Environmental Engineering to the TAC team. Professor McElmurry contacted me a few weeks ago and visited the Water Plant and took several samples from the Flint River and the distribution system.

Professor McElmurry's team has submitted a proposal to the National Institute of Environmental Health Sciences (NIEHS) for funding to evaluate how changes in the drinking water system are impacting water quality. Their project has the following goals:

- Define exposure within Flint's drinking water system using a combined sampling and modeling approach.
- Quantify how the concentrations of DBPs and Pb change over time within the water distribution system.
- Apply a high-throughput bioassay to evaluate toxicity of complex chemical mixtures (focused on DBPs).
- Communicate results to water utility operators, government officials (city, state, and federal), public health agencies and residents using principles of risk communication through a variety of channels including social media.

Given their goals and their proximity to Flint, I believe that adding Professor McElmurry to the Technical Advisory Team will bring added evaluation and data to our cause.

III. Ongoing Items of concern or in process

A. Detroit Water

Water from Detroit is now flowing through all of the transition mains and should be present at most taps throughout the City. We are flushing hydrants in a manner to help circulate water within the system, individual usage patterns will dictate water being at every household and business. We will be testing hardness and phosphate levels over the next several days across the city to verify the presence of Detroit water.

B. Service Lines

I want to clarify where we are regarding the service line data. The 45,000+ cards are only one aspect of the information and represent the original data. As work has occurred over the last several decades, the Service Center has built a second, partial set of cards with updated information. Both sets of cards are kept as permanent records with accurate data. We also have maps which were last updated in 1984 with additional information. Finishing what the City started has involved stitching together three sets of data and then putting that into a database.

U of M Flint has taken ownership of the project and they have measured how much labor it will take to complete the task. Professor Kaufman is working pro bono but has just submitted a proposal to the City for the labor required in order to complete the task. The proposal will be turned around ASAP for them to complete the work.

C. Corrosion Control

On October 19th 2015 our engineering consultant submitted a design package to the DEQ with recommended phosphate dosing. After EPA review, the comments were just returned and today LAN is discussing with DEQ when to expect final approval and permitting. There are questions regarding the elevated dose of phosphate that we will bring to the next Technical Advisory meeting for discussion. The questions will are largely around the pros and cons of the specified dose level and the public communication and expectations that should accompany the implementation.

Issue	Description	Action Item	Owner
Corrosion Control	To help recoat the piping	The final design has been sent to MDEQ for peritting.	LAN
Surge Protection	Main breaks are down.	Leak detection will continue for the next few months.	City Staff
KWA - Prep	Design and installation of final improvements needed	Internal November 5th meeting scheduled to discuss specifics. See item IV.	LAN/City
KWA - Transfer Station	Buffer for water supply from KWA	Internal November 5th meeting scheduled to discuss specifics. See item IV.	LAN
Hydraulic Model	Filling with data	Need to verify broken valve locations for model to be accurate.	LAN/City
SCADA Upgrades	Used to develop automation within the system.	First phase went in in FY15 second and final phase due to be installed prioir to KWA's arrival.	City Staff

IV. Needs for treating and using water from KWA

The City is meeting with the engineering consultants on Thursday November 5th in order to build a project timeline of all items needed to be prepared for water delivery from KWA. The following items will be discussed:

A. Design and construction of transfer station to Dort Reservoir (while in use).
   - Needed to buffer the volume of water that KWA is capable of delivering prior to their reservoir tank being activated.

B. KWA access to the plant.
   - The current design calls for use of the pipe that was empty and is now in use. An alternate plan needs to be discussed and vetted.

C. Alum feed system
   - Needed for coagulant change to raw water and to reduce chloride.

V. Testing Data

We will continue to update this data table weekly, if there is something that is missing or additional data that is requested please let me know and we will attempt to add it to the table.

Date	Flow (MGD)	pH (S.U.)	Total Hardness (mg/L)	Total Alkalinity (mg/L)	Non-carbonate Hardness (mg/L)	Chloride (mg/L)	Calcium (mg/L)	Magnesium (mg/L)	Total Phosphate (mg/L)
Range GLWA	12 - 19	7.3 - 7.6	98 - 102	70 - 76	26 - 32	11 - 13	26 - 32	3.9 - 6.3	1.0 - 1.2
10/26/2015	12	7.36	102	74	28	11	30.5	6.3	1.14

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

- The initial After Action Plan meeting was held on October 22. Topics covered were:
  - The discussion of the roles of each team member
  - The scope of the After Action Plan
  - The time frame in which the After Action Plan is to be completed

  The main components of the After Action Plan are:
  - An After Action Review Summary time line that details critical events in chronological order, asking key questions, and providing explanations for actions taken
  - Implementation of the Governor's 10-point Action Plan
  - An evaluation of if DEQ made mistakes and, if so, what they were
  - An evaluation of lessons learned, defining what we can do better/differently in the future

- Participated on an October 22 conference call with the EPA's Flint Safe Drinking Water Task Force to discuss proposed sampling protocol and the comments received from EPA. Agreed to reconvene a call next week to discuss how the pilot sampling effort goes, what went well, what might need to be adjusted, etc.

- A summary of our discussion with EPA regarding Flint's corrosion control plan was provided to Darren Lytle and Michael Schock of EPA. The summary included confirmation of the actual phosphate dosage from the Detroit Lake Huron Water Treatment Plant.

- Proper dosages are now confirmed, based on incoming phosphate residual at Flint. A product cut-sheet to confirm NSF approval and maximum dose is to be provided shortly. Flint's consultant (Lockwood, Andrews & Newnam, Inc.) will also confirm proper sizing of the feed pumps. Anticipate receiving this information on October 23, which will facilitate issuance of the Act 399 permit.

- An updated monitoring schedule is completed and signed. The schedule will be mailed to the city of Flint on October 23. A copy of the updated monitoring schedule is attached.

- An e-mail was sent to John O'Brien of Genesee County informing him of our concern over improper soil erosion control measures at the pipeline job site and what corrective measures were being taken to avoid a potential halt of construction by the Lapeer County Road Commission. Genesee County has not responded thus far.

Additional Actions:

- A conference call was held among representatives from DEQ/DLARA/DHHS to further discuss ways to ensure that the efforts of all three agencies were coordinated. It was determined that weekly calls providing updates to the group as a whole would be beneficial. DEQ also agreed to copy DLARA and DHHS on their daily update report to the Governor's office.

- Flint Action Plan Coordinator George Krisztian contacted Flint Community Schools Superintendent Bilal Tawwab to obtain permission to allow the *Detroit Free Press* to take footage of the water sampling process to be conducted at Freeman Elementary School on Saturday, October 24. Superintendent Tawwab gave his permission, stating that it would not be an issue since there would not be any students present.

- DLARA completed additional review of documents at the Flint repository to assist with the sequencing at the schools.

- Flint is able to provide DLARA plumbing inspectors with on-site workspace; additional documentation gives greater guidance on locations for plumbing fixtures.

- DLARA received confirmation from DEQ that bottles and necessary equipment will be available for sampling start on Saturday, October 24.

Attachment (Updated Monitoring Schedule)

Mr. Brent Wright
City Of Flint – D.P.W
Flint Water Plant
4500 North Dort Highway
Flint, Michigan 48505

WSSN: 02310

Dear Mr. Wright:

SUBJECT: Revised Drinking Water Monitoring Schedule – 2015
Monthly Operation Reports
Siting Plans and Record Keeping

Monitoring Schedule:

Enclosed is your revised Drinking Water Monitoring Schedule for remainder of calendar year 2015 outlining the minimum requirements for your public water supply. Your schedule has been revised based on the City's change in source of its drinking water from the treatment of the Flint River utilizing the City's Water Treatment Plant to the Great Lakes Water Authority/Detroit Water and Sewerage Department. Collect samples early in the monitoring period of the year indicated on the schedule. If you use a private laboratory you are required to report the results to us within the first ten days of the month following the month that you received the results. To receive credit for monitoring, the **"WSSN"** (water supply serial number), the **"Site Code,"** and **"County"** must appear on the sample result. Bottles will NOT be mailed automatically. If you use the Department of Environmental Quality Laboratory, you can order bottles by calling 517-335-8184. Be certain of the United States Environmental Protection Agency sampling and analysis method requirements for hold times.

Monthly Operation Report (MOR) Requirements:

The City shall submit MORs as required under Administrative Rule 1502 (R325.11502). Please note required coliform bacteria monitoring results and associated chlorine residual monitoring shall be submitted to the department within the first 10 days following the end of the required monthly monitoring period. In addition, monthly operation reports shall be submitted to the department during the month following the month for which the monthly operation report was prepared.

Disinfection By-Product Sample Siting Plans:

The City of Flint shall continue routine standard monitoring of disinfection by-products, according to your Disinfection & Disinfectants By-Product (DDBP) plan which identifies 8 sites for routine quarterly monitoring.

Lead and Copper Monitoring Requirements and Site Sample Pool

Please note distribution system monitoring for water quality parameters (WQPs) continues at the expanded set of 25 sites per quarter. Lead and copper monitoring in accordance with the requirements of Administrative Rule 710a (R325.10710a) is being required for the 6 month period between January 1, 2016 and June 30, 2016. The City must ensure its sample site pool is large enough to collect the number of lead and copper tap samples required. All sites from which first draw samples are collected shall be selected from the pool of targeted sampling sites.

The City shall also conduct additional operational monitoring to demonstrate the effectiveness of corrosion control treatment.

Record Keeping:

The City shall maintain all monitoring records in accordance with all applicable requirements under the Administrative Rules including Rule 720a (R325.10720a), Rule 1506 (R325.11506), and Rule 1507 (R325.11507).

The Michigan Safe Drinking Water Act requires certain reports to be submitted to this office each year. Please remember that cross connection reports and annual pumpage reports are due by March 31, and the **Consumer Confidence Report** is due by July 1.

Also enclosed is the document "2015 Monitoring and Reporting Requirements." This provides additional details about monitoring and reporting requirements. If you have any questions, please contact us using the information below.

Enclosure
cc/encl: Mr. Robert Bisnick, City Of Flint
Genesee County Health Department

2015 Monitoring Schedule

FLINT, CITY OF **WSSN: 02310**

Collect samples early in the monitoring period. This schedule reflects your expected routine monitoring and is subject to change. To receive credit for monitoring, include the **WSSN, Site Code, and County** on your request for analysis form. Collect Bacteriological and Automated Partial Chemistry samples close to the shipping time and send overnight delivery. Send all sample results to your Department of Environmental Quality (DEQ) district office unless you use the DEQ laboratory. Test codes, sample units, and costs are listed to help you complete the DEQ laboratory form. Prices are subject to change without notice. The DEQ laboratory is closed on state holidays.

Location: Distribution System

Sample Type	Collect Samples According to the ...	# Samples/ Frequency	Collect	Site Code	Fee	Unit Number	Test Code
Bacteriological – coliforms	TCR Sampling Site Plan	100/Monthly	**Monthly**	DIST	$16.00	30	BPTC
Chlorine Residual	DBP Monitoring Plan	If serving chlorinated water, measure the residual disinfectant level at the same point and at the same time as the bacteriological sample and report the average to the DEQ.					
Total Trihalomethanes	DBP Monitoring Plan	8/3 months	**During February, May, August and November 2015**	See DBP Monitoring Plan	$65.00	36VO	CXTM
Haloacetic Acids		8/3 months	**During February, May, August and November 2015**	See DBP Monitoring Plan	$130.00	36HA	CXHA
Water Quality Parameters	Representative Sites	25/Quarterly	**Quarterly**	DIST	Various	Various	Various
Lead Copper for Corrosion Control	Lead and Copper Sampling Pool	60/6 months	Between 1/1 and 6/30/2016	DIST	$26.00	36CC	CCUB

Community Water Supply
2015 Monitoring and Reporting Requirements

Please Monitor Early: Collect samples early in the monitoring period (month, quarter, year) of the year indicated on the schedule. Bacteriological and partial chemistry samples should be collected close to the shipping time and sent overnight delivery to assure sample holding times are not exceeded (30 and 48 hour hold times respectively). We also recommend avoiding mailing bacteriological samples immediately preceding or following a holiday because samples tend to exceed the 30 hour hold time. When this occurs, a repeat sample must be collected as soon as possible upon notification.

If you use a private laboratory please report the results to us within the first ten days of the month following the month that you received the results. A list of certified laboratories is available on request. If samples are not collected as indicated on your monitoring schedule, you will incur a monitoring violation and possibly a fine. For information on the fines policy, visit http://michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, and Administrative Fines (under Laws and Rules).

To receive credit for monitoring, you must include the **"WSSN"** (water supply serial number), the **"Site Code,"** and the **"County"** when you submit samples for analysis. Site codes are listed on your monitoring schedule.

Special Instructions If You Use The DEQ Laboratory: Bottles will NOT be mailed automatically. To order bottles, call the DEQ Laboratory at 517-335-8184 or download the form EQP 2301 *Requisition for Water Sample Units* from www.michigan.gov/deq. Click on Key Topics, Laboratory Services, Drinking Water, Obtaining The Necessary Sampling Units, and 'test list'. Please note that the DEQ laboratory is closed on most state holidays. The DEQ laboratory prices are subject to change without notice.

Special Instructions For Automated Partial Chemistry, VOC and TTHM Samples: These sample bottles must be cooled and preserved during shipment to the laboratory. If you use the DEQ laboratory, you will receive the ice pack, acid dropper (if necessary) and small cooler when you request the bottles. Samples must be preserved correctly to be used for compliance purposes. To avoid resampling follow instructions contained with the sample bottle. If you would like more information, contact the DEQ lab, at 517-335-8184, or contact this office.

Cyanide: Previously, supplies that chlorinated the water were waived from monitoring for cyanide. The U.S. EPA now requires all supplies to sample the entry point for cyanide.

UCMR3 Monitoring: You may have monitoring requirements in 2015 under the third Unregulated Contaminant Monitoring Rule (UCMR3). The U.S. EPA will contact you directly if your water supply is required to monitor in 2015. A list of laboratories certified to analyze the samples collected for UCMR3 is available at http://water.epa.gov/lawsregs/rulesregs/sdwa/ucmr/ucmr3/upload/lablist.pdf. Contact the U.S. EPA with questions.

Reminder if Lead and Copper Monitoring Due This Year: Provide individual lead tap results to people who receive water from sites that you sampled, even if lead was not detected, within 30 days of learning the results. Send us a certification that you met all the delivery requirements along with a sample copy of the customer notice within 3 months after the end of the monitoring period. Water supplies that failed to distribute the Consumer Notice of Lead Results must include the following statement in their CCR, "During the year, we failed to provide lead results to persons served at the sites that were tested as required by the Lead and Copper Rule." To download the *Lead and Copper Report and Consumer Notice of Lead Result Certificate* in Microsoft Word or PDF format, visit www.michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, and Reporting Forms (under Manuals, Forms & Brochures).

Annual Reports: These reports are due to this office each year.

- The **Cross Connection Report**, due by March 31, describes the status of your local cross connection control program. Manufactured housing communities are exempt from this requirements until 2016.

  Each year, water supplies must submit this report, even if a formal program has not been implemented. If cross connections do not exist in your water system, indicate so on the report. Download the Cross Connection Report form from http://michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, Reporting Forms (under Manuals, Forms & Brochures). Instructions are included with the form.

- The **Annual Pumpage/Usage Report**, due by March 31, is required of water supplies that do not submit monthly operation reports.

  This summary of water pumpage and water use must be submitted by each water supply that does not submit a monthly operation report. To manage our natural resources, pumpage data are compiled to determine water use demands in Michigan. Download the Annual Pumpage/Usage Report form from http://michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, Reporting Forms (under Manuals, Forms & Brochures). Please be sure to indicate the appropriate units on the report (e.g. million gallons or gallons).

- The **Consumer Confidence Report**, due by July 1 to your customers, to your local health department and to this office, describes the quality of the water and characterizes the risks, if any, from exposure to contaminants detected..

  Electronic delivery methods may be used to distribute the CCR to bill-paying customers, provided the method is direct. A paper copy must be delivered to bill-paying customers who request it or known to be unable to receive the CCR electronically. For more information on e-delivery, visit www.michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, Consumer Confidence Report Rule (under Laws and Rules).

MICHIGAN DEPARTMENT OF ENVIRONMENTAL QUALITY

PERMIT APPLICATION FOR WATER SUPPLY SYSTEMS

(CONSTRUCTION - ALTERATION - ADDITION OR IMPROVEMENT) AS DESCRIBED HEREIN

Required under the Authority of 1976 PA 399, as amended

ENTERED

This application becomes an Act 399 Permit only when signed and issued by authorized Michigan Department of Environmental Quality (DEQ) Staff. See instructions below for completion of this application.

1. **Municipality or Organization, Address and WSSN** that will own or control the water facilities to be constructed. This permit is to be issued to: City of Flint 4500 N. Dort Highway Flint, MI 48505 **WSSN:** 02310	Permit Stamp Area (DEQ use only) MICHIGAN DEPARTMENT OF ENVIRONMENTAL QUALITY PERMIT NO. W 151104 OCT 28 2015 EXAMINED AND APPROVED FOR COMPLIANCE WITH ACT 399, P.A. 1976	
2. **Owner's Contact Person** (provide name for questions): Contact: Brent Wright Title: Water Plant Supervisor Phone: 810.787.6537		
3. **Project Name** (Provide phase number if project is segmented): Flint WTP Phase II, Segment 4 Corrosion Control	4. **Project Location** (City, Village, Township): Flint, MI	5. **County** (location of project): Genesee

ISSUED UNDER THE AUTHORITY OF THE DIRECTOR OF THE DEPARTMENT OF ENVIRONMENT QUALITY

cc: DEQ RESOURCE MANAGEMENT DIVISION OCT 16 2015 LANSING DISTRICT

Issued by: Michael Prysby

Reviewed by: Michael Prysby

☐ **If this box is marked see attached special conditions.**

Instructions: Complete items 1 through 5 above and 6 through 21 on the following pages of this application. Print or type all information except for signatures. Mail completed application, plans and specifications, and any attachments to the DEQ District Office having jurisdiction in the area of the proposed construction.

Please Note:

a. This **PERMIT** only authorizes the construction, alteration, addition or improvement of the water system described herein and is issued solely under the authority of 1976 PA 399, as amended.
b. The issuance of this **PERMIT** does not authorize violation of any federal, state or local laws or regulations, nor does it obviate the necessity of obtaining such permits, including any other DEQ permits, or approvals from other units of government as may be required by law.
c. This **PERMIT** expires two (2) years after the date of issuance in accordance with R 325.11306, 1976 PA 399, administrative rules, unless construction has been initiated prior to expiration.
d. Noncompliance with the conditions of this permit and the requirements of the Act constitutes a violation of the Act.
e. Applicant must give notice to public utilities in accordance with 1974 PA 53, (MISS DIG), being Section 460.701 to 460.718 of the Michigan Compiled Laws, and comply with each of the requirements of that Act.
f. All earth changing activities must be conducted in accordance with the requirements of the Soil Erosion and Sedimentation Control Act, Part 91, 1994 PA 451, as amended.
g. All construction activity impacting wetlands must be conducted in accordance with the Wetland Protection Act, Part 303, 1994 PA 451, as amended.
h. Intentionally providing false information in this application constitutes fraud which is punishable by fine and/or imprisonment.
i. Where applicable for water withdrawals, the issuance of this permit indicates compliance with the requirements of Part 327 of Act 451, Great Lakes Preservation Act.

6. **Facilities Description** – In the space below provide a detailed description of the proposed project. Applications without adequate facilities descriptions **will be returned**. SEE EXAMPLES BELOW. Use additional sheets if needed.

The project entails installation of phosphate feed systems at both Control Station #2 (CS#2) and Pump Station #4 (PS#4). Feed at CS#2 will provide the ability to add phosphate for corrosion control to finished water supplied from the Detroit Water & Sewer Department (DWSD). Feed at PS#4 will provide the ability to add phophate to finished water to supply from either the Flint River or Lake Huron via the Karegondi Water Authority (KWA). Both feed systems are temporary systems until the planned filter transfer pump station is constructed. A permanent phosphate feed system will be constructed as part of that contract.

The feed rate will be proportionally controlled based on the water flow rate and will be tied to the existing SCADA system. See attached basis of design for more detailed information.

EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES	
Water Mains	500 feet of 8-inch water main in First Street from Main Street north to State Street. **OR** 250 feet of 12-inch water main in Clark Road from an existing 8-inch main in Third Avenue north to a hydrant.
Booster Stations	A booster station located at the southwest corner of Third Avenue and Main Street, and equipped with two, 15 Hp pumps each rated 150 gpm @ 200 feet TDH. Station includes backup power and all other equipment as required for proper operation.
Elevated Storage Tank	A 300,000 gallon elevated storage tank located in City Park. The proposed tank shall be spherical, all welded construction and supported on a single pedestal. The tank shall be 150 feet in height, 40 feet in diameter with a normal operating range of 130 – 145 feet. The interior coating system shall be ANSI/NSF Standard 61 approved or equivalent. The tank will be equipped with a cathodic protection system, and includes a tank level control system with telemetry.
Chemical Feed	A positive displacement chemical feed pump, rated at 24 gpd @ 110 psi to apply a chlorine solution for Well No. 1. Chlorine is 12.5% NaOCL, ANSI/NSF Standard 60 approved and will be applied at a rate of 1.0 mg/l of actual chlorine.
Water Supply Well	Well No. 3, a 200 foot deep well with 170 feet of 8-inch casing and 30 feet of 8-inch, 10 slot screen. The well will be equipped with a 20 Hp submersible pump and motor rated 200 gpm @ 225 feet TDH, set at 160 feet below land surface.
Treatment Facilities	A 5 million gpd water treatment plant located at the north end of Second Avenue. The facility will include 6 low service pumps, 2 rapid mix basins, 4 flocculation/sedimentation basins, 8 dual media filters, 3 million gallon water storage reservoir and 6 high service pumps. Also included are chemical feed pumps and related appurtenances for the addition of alum, fluoride, phosphate and chlorine.

General Project Information – Complete all boxes below.

7. Design engineer's name, engineering firm, address, phone number, and email address:

Jeremy Nakashima, PE
Lockwood, Andrews and Newnam, Inc.
1311 South Linden Rd, Suite B
Flint, MI 48532
jnnakashima@lan-inc.com

8. Indicate who will provide project construction inspection:
☐Organization listed in Box 1.
☒Engineering firm listed in Box 7.
☐Other - name, address, and phone number listed below.

9. Is a basis of design attached?
☒YES ☐NO

If no, briefly explain why a basis of design is not needed.

10. Are sealed and signed engineering plans attached?
☒YES ☐NO

If no, briefly explain why engineering plans are not needed.

11. Are sealed and signed construction specifications attached?
☒YES ☐NO

If specifications are not attached, they need to be on file at DEQ.

12. Were Recommended Standards for Water Works, Suggested Practice for Water Works, AWWA guidelines, and the requirements of Act 399 and its administrative rules followed?
☒YES ☐NO

If no, explain which deviations were made and why.

13. Are all coatings, chemical additives and construction materials ANSI/NSF or other adequate 3rd party approved?
☒YES ☐NO

If no, describe what coatings, additives or materials did not meet the applicable standard and why.

14. Are all water system facilities being installed in the public right-of-way or a dedicated utility easement? (For projects not located in the public right-of-way, utility easements must be shown on the plans.)
☒YES ☐NO

If no, explain how access will be obtained.

15. Is the project construction activity within a wetland (as defined by Section 324.30301(d)) of Part 303, 1994 PA 451?
☐YES ☒NO

If yes, a wetland permit must be obtained.

16. Is the project construction activity within a 100-year floodplain (as defined by R 323.1311(e)) of Part 31, 1994 PA 451, administrative rules?
☐YES ☒NO

If yes, a flood plain permit must be obtained.

17. Is the project construction activity within 500 feet of a lake, reservoir, or stream?
☐YES ☒NO

If yes, a Soil and Erosion Control Permit must be obtained or indicate if the owner listed in box 2 of this application is an Authorized Public Agency (Section 10 of Part 91, 1994 PA 451) ☐ Owner is APA.

18. Will the proposed construction activity be part of a project involving the disturbance of five (5) or more acres of land?
☐YES ☒NO
If yes, is this activity regulated by the National Pollutant Discharge Elimination System storm water regulations?
☐YES: NPDES Authorization to discharge storm water from construction activities must be obtained.

☒NO: Describe why activity is not regulated:
Please call 517-241-8993 with questions regarding the applicability of the storm water regulations.

19. Is the project in or adjacent to a site of suspected or known soil or groundwater contamination?
☐YES ☒NO

If yes, attach a copy of a plan acceptable to the DEQ for handling contaminated soils and/or groundwater disturbed during construction. Contact the local DEQ district office for listings of Michigan sites of environmental contamination.

20. IF YOU ARE A CUSTOMER/WHOLESALE/BULK PURCHASER, COMPLETE THE FOLLOWING

1) Name and WSSN of source water supply system (seller) _____

2) Does the water service contract require water producer/seller to review and approve customer/wholesale/bulk purchaser water system construction plans?
☐YES ☐NO

If yes to #2, the producer/seller approval letter must be attached when submitted to DEQ.

21. **Owner's Certification** The owner of the proposed facilities or the owner's authorized representative shall complete the owner's certification. It is anticipated that the owner will either be a governmental agency (city, village, township, county, etc.) or a private owner (individual, company, association, etc.) of a Type I public water supply.

OWNER'S CERTIFICATION

I, BRENT F WEIGHT (print) (name), acting as the PLANT SUPERVISOR (print) (title/position) for CITY OF FLINT WATER PLANT (print) (entity owning proposed facilities) certify that this project has been reviewed and approved as detailed by the Plans and Specifications submitted under this application, and is in compliance with the requirements of 1976 PA 399, as amended, and its administrative rules.

Signature* 10-16-2015 Date (810) 787-8537 Phone

*Original signature only, no photocopies will be accepted.

PROJECT BASIS OF DESIGN – FOR WATER MAIN PROJECTS

PROJECT NAME: Flint WTP Phase II, Segment 4 Corrosion Control

For this PROJECT the following information must be provided per Act 399 unless waived by the Department. For projects other than water main installation, or if additional space is needed, attach separate sheet(s) with detailed Basis of Design calculations.

A. A general map of the initial and ultimate service areas
☒ Included on engineering plans ☐ Attached separately

B. Number of service connections served by this permit application all customers

C. Total number of service connections ultimately served by entire project all customers

D. Residential Equivalent Units (REUs) served by this permit application _____

E. Total Residential Equivalent Units (REUs) ultimately served by entire project _____

F. Water flow rates for proposed project based on REUs listed in "D" and "E" above

1. Initial design average day flow (mgd)	18.3
2. Initial design maximum day flow (mgd)	25.4
3. Total design average day flow (mgd)	24.0
4. Total design maximum day flow (mgd)	36.0
5. Required fire flows: (1)	_____ gpm for _____ hours

G. Actual flows and pressures of existing system at the connection point(s) (2)

_____ gpm at _____ psi
_____ gpm at _____ psi
_____ gpm at _____ psi
_____ gpm at _____ psi

H. Estimated minimum flows and pressures within the proposed water main system (3)

_____ gpm at _____ psi

(1) Every water system must decide what levels of fire fighting flows they wish to provide. Fire flow should be appropriate for the area (residential, commercial, industrial) being served by the project. Typical fire flow rates can be obtained from the water supply, local fire dept., ISO or AWWA. The water system must then be designed to be able to provide the required fire flows while maintaining at least 20 psi in all portions of the distribution system.

(2) Flows and pressures at the connection points must be given to determine if the existing water main(s) are able to deliver water to the new service area. These numbers can be obtained from a properly modeled and calibrated distribution system hydraulic analysis or hydrant flow tests performed in the field. If more than one connection is proposed, list as needed.

(3) List what the estimated minimum flows can be expected in the proposed water mains based on estimated water demands, head losses, elevation changes and other factors that may affect flows, such as dead end mains.

City of Flint
Phase II, Segment 4 Corrosion Control
Basis of Design

Given that Flint will require lead and copper corrosion control and given that Detroit utilizes orthophosphate for their corrosion control methodology, and that Flint will be receiving Detroit water for the immediate future, orthophosphate is the appropriate corrosion control methodology for Flint. A dosage of 0.8 mg/l as PO_4 has been recommended for the Detroit water. Numerous utilities utilizing Lake Michigan water have a target dosage of 0.9 mg/l as PO_4. Therefore, a target dosage in the range of 0.8 to 0.9 mg/l appears appropriate.

It is expected that initially there will be a significant PO_4 demand in the system. This will require a significantly higher dosage until this demand is satisfied and the target residual can be maintained. We are therefore designing for capability of a maximum dosage of 1.5 mg/l.

The arriving Detroit water will likely have some residual PO_4 when it arrives at Flint. It has been reported that this residual will be approximately 0.4 mg/l. The system must therefore be capable of a minimum dosage of 0.4 mg/l.

Based upon the usage of 75% Phosphoric Acid and a flow range of 4 MGD to 25 MGD, with an average day of 16 MGD, the expected feed rate will be 1.35 to 32 gpd. Average Phosphoric Acid feed is expected to be 10.8 gpd, requiring 30 days storage of 325 gal. Phosphoric acid will be stored in delivered totes and will be placed with containment pallets for dual containment.

Orthophosphate will need to be applied at two locations. Detroit water will enter the Flint system at Control Station CS2, and supplementary phosphate will be applied there. However, on occasion some incoming water may need to be diverted to the Dort Reservoir, bypassing CS2. This water would then be introduced to the system through High Service Pump Station PS4 and phosphate would be introduced at this location.

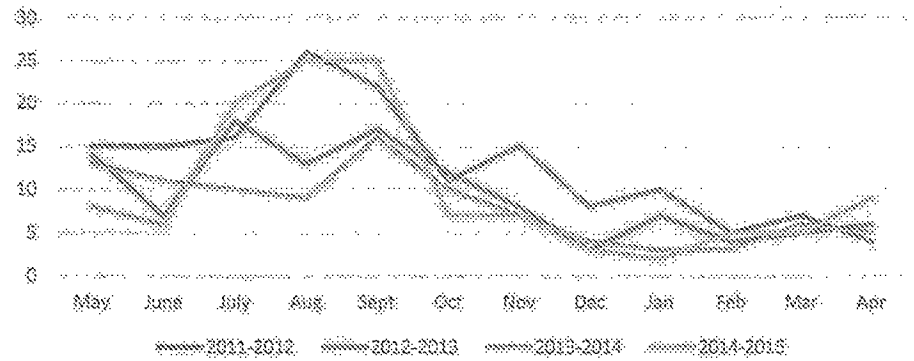
Subject: RE: Director's Office Assignment -- Flint - need update asap

I apologize for the delay in responding more specifically to this assignment, it took some time to review our Childhood Lead Poisoning Prevention program data to see if it might contribute to the understanding of the situation in Flint with their water supply. Here is what we found:

We looked at lead testing results for May 2014-April 2015, which is the 12 month time frame just after Flint started drawing their water from the river (water source changed in April 2014).

We compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more



often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015.

So upon review, we don't believe our data demonstrates an increase in lead poisoning rates that might be attributable to the change in water source for Flint. We recognize that lead exposure via the water is only a small piece of what may be happening for families in Flint, however, we hope the information is helpful.

Subject: Follow Up from our Aug. 4th meeting

Dear Ms. Walters,

I wanted to update you regarding our Department's findings related to questions raised during our meeting at the Governor's office on August 4. I apologize for the delay in getting back to you.

Lead and Copper Monitoring

Regarding Flint lead and copper compliance monitoring for the January – June 2015 period, the City has confirmed that all lead and copper samples collected throughout the City, whether routine sites or customer requests, were sent to the State of Michigan lab for analysis. Individual sample results are provided to the property owner within 30 days of receiving the lab results in accordance with the Michigan Safe Drinking Water Act (Public Act 399, 1976 Administrative Rule 410(5). Results from the State of Michigan lab are provided directly to our Office.

Staff have confirmed that the lead 90th percentile compliance calculation of 11 parts per billion is based on 69 samples that met the appropriate sampling location site criteria, and met the sample collection site and collection protocol requirements of the Safe Drinking Water Act for this monitoring period. A minimum of 60 samples were required for this monitoring period. As indicated during the meeting, the City's sampling for lead complies with the Action Level standard of 15 parts per billion, but based on the population served by the City and these results, the City will need to make a recommendation to the MDEQ on how they will fully optimize their corrosion control treatment. These next steps continue to follow the requirements of the Lead and Copper Rule.

Samples collected at your residence of 212 Browning Avenue were not included this compliance determination as you utilize a whole home filter. As stated in the Michigan Safe Drinking Water Act (Public Act 399, 1976 Administrative Rule 710a, Lead and Copper in tap water; monitoring requirements) "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment alters the water chemistry and water quality such that it is no longer representative of public water from the City's distribution system. Therefore, the City cannot use samples collected at your residence as part of its determination for public water system compliance with the lead or copper action level standard.

Sample Summary (samples taken at your residence)

For your information, we are providing the information that we've gathered regarding samples collected at your home. Our records indicate between February and June of this year there were six samples collected by either you or Mr. Mike Glasgow with the City of Flint, and submitted to the State Laboratory for analysis as follows:

February 11, Bathroom tap, collected at 10:20 AM by Mike Glasgow. This sample was analyzed for aesthetic metals (copper, iron, manganese, and zinc) which does not include lead analysis.

February 18, Kitchen tap, collected at 7:15 AM by you. This sample was analyzed for lead (104 parts per billion) and copper (non-detect).

February 25, Kitchen tap, collected at 10:26 AM by Mike Glasgow. This sample was analyzed for metals including lead. All results (including lead) were non-detect except for Barium 0.01 parts per million. The result for Barium was well below its maximum contaminant level of 2 parts per million.

March 3, Kitchen tap, collected at 6:00 AM by you. This sample was analyzed for lead (397 parts per billion) and copper (non-detect).

March 18, Kitchen tap, collected at 11:10 AM by Mike Glasgow. This sample was analyzed for lead (4 parts per billion) and copper (non-detect).

April 2, Pre-point of service, collected at 8:00 AM by you. This sample was analyzed for lead (707 parts per billion) and copper (110 parts per billion).

Lead Education/Outreach

As we discussed during the meeting, we support efforts to educate homeowners about the sources of lead in their private residence, provide guidance measures to reduce the potential for lead exposure, and provide information on resources for lead abatement. Along those lines, our Office has been in contact with the Department of Health and Human Services, Environmental Health Division, Healthy Homes Section and had some preliminary discussions about a public education and assistance campaign regarding household lead issues, guidance and abatement.

Lead monitoring by public water systems serves a dual purpose. The first purpose is to ensure the public water supply is adequately treating its water to address corrosion potential and help limit lead exposure. The second purpose is to inform homeowners about lead levels within their individual residence so that they can make educated choices regarding their own exposure risk.

pH Results

During the meeting concerns were also expressed regarding pH levels within customer plumbing systems. As you may know, pH has no associated contaminant level as it is simply a numeric scale used to specify the acidity or alkalinity of a solution. The City of Flint conducts daily monitoring of pH values on both its raw and finished (treated) water at the City's water treatment plant as part of its operations. The City is also required to conduct water quality parameter monitoring in the distribution system, which includes pH. Samples are analyzed in accordance with Standard Methods using properly calibrated analytical equipment. Results for pH from these samples are summarized below.

Since late April 2014 – June 2015, the following pH conditions were reported:

Water Treatment Plant – Finished Water plant tap pH range = 7.07 minimum to 9.9 maximum, overall average 7.7, measured daily. We believe the 9.9 is a one- time anomaly from softening treatment.

Distribution System – Water Quality Parameters taken from 25 sample sites located throughout and monitored quarterly
July – Sept. 2014: pH 7.71 average, range 7.56 – 7.86
Oct. – Dec. 2014: pH 7.88 average, range 7.62 – 8.10
Jan. – March 2015: pH 7.81 average, range 7.60 – 7.99
April – June 2015: pH 7.63 Average, range 7.48 – 7.80

In addition, the City's treated water contains alkalinity, which is a measurement of the buffering capacity of water to resist a change in pH. As you can see from the water quality parameter monitoring results above there has been very little change in pH within the City's distribution system. The pH levels described within customer site piping or premise plumbing systems are believed to be the result of onsite treatment and not representative of water quality shown to be occurring in the public water supply system.

Consumer Confidence Report

Finally, there was confusion during the meeting regarding the City's annual water quality report, the Consumer Confidence Report which we have since been able to clarify.

The City of Flint issued two separate Consumer Confidence Reports (CCR's) in 2015 covering the water quality data from 2014. One report was for the period of January – April 2014 when the City was obtaining water from Detroit (DWSD). And a second report was for the period April – December 2014 when the City was using the Flint River and its own Water Treatment Plant.

The CCR for DWSD water was mailed to customers in June. The Flint River based CCR was mailed to customers in mid-July, delayed due to issues with the printing contractor. We agree that having two separate reports caused confusion. We are working with the City to ensure both reports are posted to the City's website and both are made available when requested by customers. Should the City choose to create separate CCR's during the year that the City of Flint connects to the Karegnondi Water Authority we will work with the City to provide more clarity and try to have all material included in a single mailing.

The DWSD based CCR is the one community members had at the meeting, while the DEQ brought a copy of the Flint River based CCR. As separate and distinct sampling was done under each source, this explains the discrepancy in the values and monitoring periods being reported in the respective CCR's.

We appreciate your interest in these matters and hope this has addressed many of the questions brought up during our meeting. I would like to provide this information to both Dr. Sullivan and Ms. Mayes, but I do not have their contact information. I'm hoping you can share this with them and any others that may be interested.

Sincerely,

Liane J. Shekter Smith, P.E., Chief
Office of Drinking Water and Municipal Assistance
Michigan Department of Environmental Quality

February 17, 2015

Honorable Mayor Dayne Walling
& Members of the City Council
1101 South Saginaw Street
Flint, Michigan 48502

RE: City of Flint Municipal Drinking Water System
Initial Water Quality Investigation and Water Rate Issues

Ladies and Gentlemen:

I would like to thank the Office of the Mayor and City Council Members for extending such a warm welcome to me on my recent visit to the City of Flint this past weekend. Flint, Michigan enjoys a wonderful history and is part of what has made America strong. Clearly, the City of Flint is a community in transition.

While my initial visit focused on the water supply and immediate concerns for the health and safety of the community water supply, the following recommendations are broader in scope and are meant to be purely constructive.

Source Supply Evaluation

- Update and implement the Source Water Protection Plan.
- Define and identify groundwater quality and quantity inflow variables to the Flint River, specifically from the contaminated sources identified adjacent to the river.
- Define and identify reservoir release surface water quality and quantity variables to the Flint River, specifically from the Holloway Reservoir.
- Thoroughly evaluate the Detroit Water Supply quality characteristics.
- Conduct a detailed "cost of treatment assessment" of the Flint River Water Treatment Plant and compare it directly to the cost per unit of water purchased from Detroit. Publish said results and allow for public input as to the choice of water supplied based upon actual costs versus quality.

405 North Indian Hill Boulevard
Claremont, CA 91711-4600

(909) 621-1266
(909) 621-1196 Fax

Water Treatment Plant

In order to achieve immediate improvement to the water quality in the City of Flint, the following recommendations should be considered for implementation. Said recommendations are made with the intent of being migratory toward ultimate treatment of Lake Huron water from the Karegnondi Water Authority.

- Optimize the ozone disinfection system.
- Discontinue the use of sodium bisulfate to reduce pH in the ozone contact chamber.
- Trust the Plant Operator to use the optimum amount of ferric chloride required for coagulation.
- Investigate the use (jar tests) of ferric chloride and various water treatment polymers to reduce the use of corrosive ferric chloride.
- Discontinue the practice of lime softening. Continue the flow through the softener facility and consider adding a low dose of filter aid (additional polymer) as necessary during seasonal high turbidity.
- Discontinue the practice of fluoridation.
- Discontinue the practice of recarbonation.
- Discontinue the use of pre-filtration chlorine.
- Remove the anthracite coal media from the filter beds and replace it with a granular activated carbon (GAC) material. There are specifically engineered products for use in dual media filters. The use of GAC for organic Trihalomethanes (THM) precursor removal will immediately reduce THM formation in the drinking water supply.
- Post chlorinate disinfect based on residual demand requirements. Post chlorination will not be as intensive as the organic material will be dramatically reduced. The GAC will also serve as a barrier to other types of contamination events (petroleum, chemical, and algae blooms).

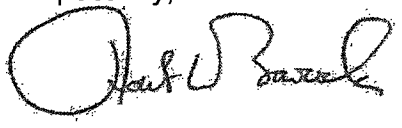
Distribution System Operations

- Complete development of the water distribution hydraulic flow model.
- Immediately increase distribution system velocities.
- Re-engineer the distribution system to encourage directional sediment transport for evacuation of system contaminates (sludge, biofilm, sediment, and other debris). This will further aid in chlorine demand management.

- Take at least one of the water system storage reservoirs out of service. Thoroughly clean the storage reservoir, perhaps a program of alternative years of service. With the 2 MG elevated tank, perhaps both reservoirs could be removed from service this year.

Budget & Rate Concerns

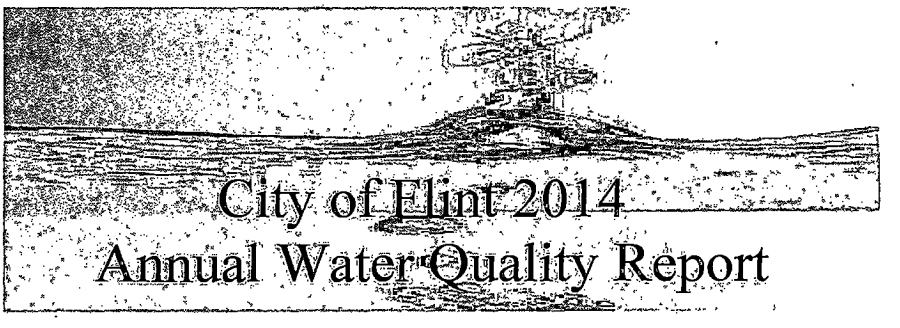
I have extremely limited information on the rate-setting program. My recommendations here are more about a process that aids communities with transparency. I have been advised to look at a recent study by one of the local colleges; further, I would need access to a detailed budget and expenditure accounting to provide more specific recommendations.



- Prepare a budget that accounts for all fixed/variable debts: loans, capital depreciation of infrastructure, retirement system obligations, etcetera. This will allow the community to understand exactly where it stands in relation to its debt obligations... before one drop of water is produced. The total of the compilation can then be divided among the consumers based on number and class size of services. It is simple, straightforward, and easily understood.

- Prepare a budget that accounts for all commodity/variable costs: salaries, chemicals, energy, contract services, etcetera. This will allow the community to understand exactly where it stands as it relates to the cost of water. Using historic production and sales numbers, project a water sales figure and divide the commodity costs among the units; this is the true cost of water.

Again, this recommendation letter is very limited in scope. I will continue to make myself available to you and members of the community to answer questions.



The City of Flint, while consulting with the Michigan Department of Environmental Quality, must begin to set its own parameters for compliance with the Safe Drinking Water Act. You have a very well qualified staff at the Flint River Surface Water Treatment Plant and they need to be given the latitude and flexibility to get the job done. I am not in anyway advocating violation of the Safe Drinking Water Act... indeed the recommendations I have made should help bring the City of Flint closer to the actual spirit of compliance as opposed to just meeting the statutory requirements.

Respectfully,

Bob Bowcock
Integrated Resource Management, Inc.

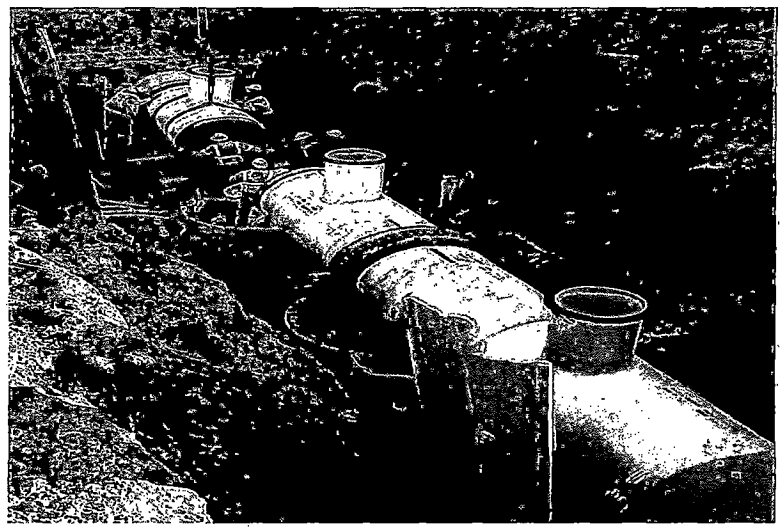
Howard Croft



The Consumers Annual Water Quality Report provides important information about your drinking water. This report includes information about the source of the water, health information, a chart summarizing regulatory required testing results, and a table giving explanations of important terms to understand when viewing the test results. The City of Flint Department of Utilities is dedicated to providing quality drinking water to the residents of the community. The Flint Water Plant operates and maintains a certified drinking water laboratory to assure compliance with all state and federal regulations, and is committed to prompt and thorough notification to the consumers if there is any reason for concern about the quality of the drinking water. Information about your drinking water is available on the City of Flint web page at *www.cityofflint.com* or by calling the City of Flint Water Plant at (810) 787-6537. The Safe Drinking Water Hotline at (800) 426-4791 is a resource for health related questions and water quality issues. General drinking water information can also be found on the USEPA web site at www.epa.gov/safewater/.

Water Source

The City of Flint began using the Flint River as a water source in May of 2014. Flint is located roughly in the middle of the Flint River Watershed. The Flint River watershed includes Holloway Reservoir, C.S. Mott Lake, Kearsley Lake, and numerous streams and creeks that drain to these lakes or directly into the Flint River. The Michigan Department of Environmental Quality in partnership with the U.S. Geological Survey, and the City of Flint Utilities Department conducted a source water assessment in February 2004 to determine the susceptibility of potential contamination. The susceptibility rating is a seven-tiered scale ranging from "very low" to "very high" based primarily on geologic sensitivity, water chemistry, and contaminant sources. The Flint River source water intake is categorized as having a very high susceptibility to potential contaminant sources.

The use of the Flint River as a source water for the City of Flint Water Treatment Plant was a temporary move, driven largely by economics and the financial state of the City. The City of Flint joined the Karegnondi Water Authority (KWA) in 2010. The KWA consists of a group of local communities that decided to support and fund construction of a raw water pipeline to Lake Huron. The KWA will provide the City of Flint Water Treatment Plant with source water from Lake Huron. The KWA pipeline is currently under construction, and is scheduled to be completed by the end of 2016.

KWA pipeline construction

General Information

In order to ensure that tap water is safe to drink, the EPA prescribes regulations, which limit the amount of certain contaminants in water provided by the public water systems. The Food and Drug Administration (FDA) regulations establish limits for contaminants in bottled water, which must provide the same protection for public health. Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the EPA's Safe Drinking Water Hotline (800-426-4791).

The sources of drinking water (both tap water and bottled water) include rivers, lakes, streams, ponds, reservoirs, springs, and wells. As water travels over the surface of the land or through the ground, it dissolves naturally occurring minerals and, in some cases, radioactive material, and can pick up substances resulting from the presence of animals or from human activity. Contaminants that may be present in source water include:

- **Microbial contaminants;** such as viruses and bacteria, which may come from sewage treatment plants, septic systems, agricultural livestock operations, and wildlife.
- **Inorganic contaminants;** such as salts and metals, which can be naturally-occurring or result from urban storm water runoff, industrial or domestic wastewater discharges, oil and gas production, mining, or farming.
- **Pesticides and herbicides;** which may come from a variety of sources such as agriculture, urban storm water runoff, and residential uses.
- **Organic chemical contaminants;** including synthetic and volatile organic chemicals, which are by-products of industrial processes and petroleum production, and can also come from gas stations, urban storm water runoff, and septic systems.
- **Radioactive contaminants;** which can be naturally occurring or be the result of oil and gas production and mining activities.

General Information (cont.)

Some people may be more vulnerable to contaminants in drinking water than the general population. Immuno-comprised persons such as persons with cancer undergoing chemotherapy, persons who have undergone organ transplants, people with HIV/AIDS or other immune system disorders, some elderly, and infants can be particularly at risk from infections. These people should seek advice about drinking water from their health care providers. EPA/CDC guidelines on appropriate means to lessen the risk of infection by Cryptosporidium and other microbial contaminants are available from the Safe Drinking Water Hotline (1-800-426-4791).

If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Infants and young children are typically more vulnerable to lead in drinking water than the general population. It is possible that the lead levels at your home may be higher than at other homes in the community as a result of materials used in your home's plumbing Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. The City of Flint Department of Utilities is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. If you are concerned about elevated lead levels in your home's water, you can minimize your potential exposure to lead in your water by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at http://www.epa.gov/safewater/lead.

2014 & Current Drinking Water Issues

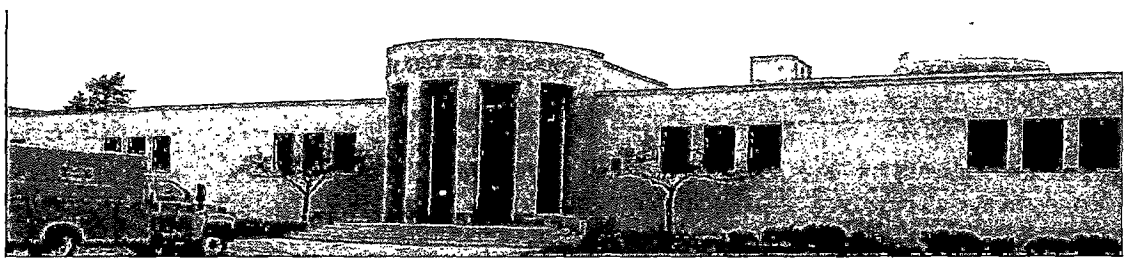
The City of Flint did experience drinking water issues in the summer of 2014. Issues began with areas of the city experiencing "rusty" water. This was largely due to the fact that the city distribution system contains hundreds of miles of cast iron pipe. As these pipes age and degrade, iron is released, causing the water to exhibit color. The change in source water, water main breaks, and routine maintenance to the system also contributed to this problem.

The City of Flint received violations from the Michigan Department of Environmental Quality (MDEQ). The violations included a total coliform and E. coli in August and September of 2014, and a corresponding total trihalomethanes (TTHM) violation in December of the same year. As the city distribution system testing began to detect bacteria, system flushing increased, and chlorine addition to the water at the treatment plant also increased. The resulting increased chlorine addition then resulted in the higher formation of trihalomethanes.

While facing these issues, the City of Flint took steps to confer with industry professionals and state regulators in regards to treatment plant operation and distribution system operation. In November, TTHM levels were below the Maximum contaminant level set forth in the Michigan Safe Drinking Water Act.

Moving Forward

The City of Flint has taken many steps to correct the underlying issues that resulted in the drinking water violations. Water Treatment Plant corrective actions that were taken immediately after the issues occurred included:



- Limiting the use of storage reservoirs during the warm weather months.
  - Warm water temperatures and water age are large contributors to the formation of THM's.
- Optimizing ozone pretreatment by updating control programming along with cleaning and inspection of the ozone generators.
  - Ozone is a powerful oxidant that provides a level of disinfection along with taste and odor control.
- Currently finalizing the installation of granular activated carbon (GAC) to the filtration process, which should be complete by the end of July 2015.
  - GAC will reduce THM's by removing the chemical precursors that react with chlorine to form the THM's.

Moving Forward (cont.)

Distribution system corrective actions that were enacted include:

- Increased water main flushing in an effort to alleviate stagnant water.
- Update distribution system water hydraulic model, to determine possible problem areas.
- Repaired or replaced several large water main valves, which were inhibiting the designed flow of water through the system.
- Planning and budgeting of 24' transmission water main repair in area of concern in the distribution system.
- Begin a complete distribution system evaluation of the 7000 water main valves that control the flow of water throughout the city. This project will be complete in July of 2015 and will provide information on where to proceed with further repairs and future projects.

The City of Flint is dedicated to resolving the issues that are facing the water system, and will continue to move forward as we prepare for the future. The City would like to thank all the residents and customers for their patience and understanding as we face the challenges ahead. The trials and tribulations that we have faced with the switch to the Flint River as a source water will prove to be important as we move ahead as a member of the KWA. Some of the distribution system issues experienced in 2014 while using the Flint River may also have been experienced with a different source water. As we continue to address the issues and take steps to be proactive, we can assure a future of quality drinking water in the City of Flint.

If you have any questions about this report or other concerns please contact the City of Flint Water Plant (810) 787-6537.

2014 Regulated Detected Contaminants
Monitored at Treatment Plant

Regulated Contaminant	Unit of Measure	MCLG	MCL	Highest Level Detected	Range of Detection	Violation
Inorganic Chemicals						
Fluoride	mg/L	4	4			No
Nitrate	mg/L	10	10	0.5	0 – 0.5	No
Metals						
Barium	mg/L	2	2	0.03	0.02 – 0.03	No
Selenium	mg/L	0.05	0.05	0.001	0 – 0.001	No
Pesticides						
Atrazine	mg/L	0.03	0.03	0.0003	0 – 0.0003	No
Organics						
Total Xylenes	mg/L	10	10	0.0005	0 – 0.0005	No

More than 100 other chemicals were monitored throughout the year that were not detected. The list of various classifications these chemicals are associated with include metals, carbamates, herbicides, pesticides, organics, and radiological.

Total Organic Carbon, TOC			
Regulated Contaminant	Required Monthly % Removal	Minimum Monthly % Removal	Monthly % Removal Ranges
Total Organic Carbon	50	53	53 - 68

Finished water and Source water samples are collected and analyzed monthly to calculate percent removal. Total organic carbon includes numerous chemicals that are found naturally in surface waters. Certain chemicals found in this group are precursors to the disinfection byproducts trihalomethanes and haloacetic acids.

Turbidity		
Highest Single Measurement (Cannot exceed 1NTU)	Lowest Monthly % of Samples Meeting Turbidity Limit (< 0.3 NTU in 95% of samples)	Violation
0.22	99.1	No

Turbidity is a measure of the apparent cloudiness of water, usually attributed to particulate matter. The turbidity data in the chart above is measured from the water plant tap every 4 hours. Turbidity is monitored throughout each stage of the treatment process in 4 hour intervals, and in one of the final stages of treatment, filtration, turbidity is monitored continuously with in line meters, and verified every 4 hours in the laboratory.

In 2014, the EPA required the City of Flint and other communities to conduct further testing on unregulated contaminants at the treatment plant and the maximum residence time in the distribution system. The monitoring results will be utilized by the EPA to determine if these chemicals should be regulated. The unregulated contaminant monitoring that yielded results are presented in the chart below

Unregulated Contaminant Monitoring			
Regulated Contaminant	Unit of Measure	Highest Level Detected	Range of Detection
Chromium	ug/L	0.40	0 – 0.4
Hexavalent Chromium	ug/L	0.40	0.34 – 0.40
Strontium	ug/L	130	120 – 130
Vanadium	ug/L	0.20	0 – 0.20

2014 Regulated Detected Contaminants
Monitored in Distribution System

Disinfectant Residuals						
Regulated Contaminant	Unit of Measure	MCLG	MCL	Highest Level Detected	Range of Detection	Violation
Total Chlorine Residual	mg/L	4.0	4.0	3.5	0.1 – 3.5	No

Microbiological Contaminants				
Regulated Contaminant	MCL G	MCL	Highest Number detected (in 1 month)	Violation
Total Coliform bacteria	0	The presence of coliform bacteria in > 5% of monthly samples	15	Yes
E. coli Bacteria	0	0	1	Yes

Disinfectant residuals and microbiological contaminants are monitored at 8 locations throughout the city distribution system, and at the 2 drinking water reservoirs and pump stations located out in the distribution system. At least 100 samples are collected and analyzed each month.

Lead & Copper						
Regulated Contaminant	Unit of Measure	MCLG	Action Level AL	90th Percentile Value	Number of samples over AL	Violation
Lead	ug/L	0	15	6	2	No
Copper	mg/L	1.3	1.3	0.11	0	No

Lead and copper monitoring was conducted from June through December 2014 with the collection of 100 samples. Samples were collected by residents from the taps at their residence. Thank you to all who participated in collecting samples.

Disinfection By-Products						
Regulated Contaminant	Unit of Measure	MCL G	MCL	Highest Level Detected	Range of Detection	Violation
Total Trihalomethanes (TTHM)	ug/L	n/a	80	196	33.3 -196.2	Yes
Haloacetic Acids (HAA)	ug/L	n/a	60	64	5 - 64	No
Bromate	ug/L	10	10	23	0 - 23	No

Disinfection by-products occur as a result of the water treatment process. Bromate is formed as a result of using ozone as a treatment additive. Ozone is used to help control taste and odor issues, and as a pre-treatment disinfection. Naturally occurring bromide reacts with Ozone to generate bromate. Bromate is monitored monthly, and compliance is based on a yearly average.

TTHM's and HAA's are formed as a result of utilizing chlorine in the treatment process. Naturally occurring compounds known as TOC's (total organic carbon) react with chlorine to form TTHM's and HAA's. The temperature and the age of water increase the formation of THM's and HAA's, and as a result, during the warm months of the year is when levels were at their highest. Samples are tested quarterly from 8 sites throughout the distribution system and compliance is based on a running annual average at each individual site.

Key to the Detected Contaminant Tables		
Symbol	**Abbreviation for**	**Definition/Explanation**
>	Greater than	
AL	Action Level	The concentration of a contaminant, which, if exceeded, triggers treatment or other requirements which a water system must follow.
HAA5	Haloacetic Acids	HAA5 is the total of bromoacetic, chloroacetic, dibromoacetic, dichoroacetic, and trichloroacetic acids. Compliance is based on the total .
LRAA	Locational Running Annual Average	
MCL	Maximum Contaminant Level	The highest level of a contaminant that is allowed in d water. MCLs are set as close to the MCLGs as feasible using the best available treatment technology.
MCLG	Maximum Contaminant Level Goal	The level of contaminant in drinking water below which there is no known or expected risk to health.
mg/L	Milligrams per Liter	A milligram = 1/1000 gram 1 milligram per liter is equal to 1ppm
MRDL	Maximum Residual Disinfectant Level	The highest level of disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.
MRDLG	Maximum Residual Disinfectant Level Goal	The level of a drinking water disinfectant below which there is no known or expected risk to health. MRLDG's do not reflect the benefits of the use of disinfectants to control microbial contaminants.
n/a	Not Applicable	
ND	Not Detected	
NTU	Nephelometric Turbidity Units	Measures the cloudiness of water.
pCi/L	Picocuries per Liter	A measure of radioactivity. Picocurie (pCi) means the quantity of radioactive material producing 2.22 nuclear transformations per minute.
ppb	Parts Per Billion (one in one billion)	The ppb is equivalent to micrograms per liter. A microgram = 1/1000 milligram.
ppm	Parts Per Million (one in one million)	The ppm is equivalent to milligrams per liter. A milligram = 1/1000 gram.
RAA	Running Annual Average	
TT	Treatment Technique	A required process intended to reduce the level of a contaminant in drinking water.
TTHM	Total Trihalomethanes	Total Trihalomethanes is the sum of chloroform, bromodichloromethane, dibromoochloromethane and bromoform. Compliance is based on total.
ug/L	Micrograms per Liter	A microgram = 1/1,000,000 gram 1 microgram per liter is equal to 1ppb

FLINT WATER PLANT

City of Flint
Water Plant & Facilities

2014 Consumers Annual Report on Water Quality

The City of Flint Department of Utilities is dedicated to providing high quality drinking water to the residents of the community. The Consumers Annual Report on Water Quality provides important information about your drinking water. This report includes information about the source of the water, health information, a chart summarizing United States Environmental Protection Agency (USEPA) required testing results, and a table giving explanations of important terms to understand when viewing the test results. The Flint Water Plant & Facilities operates and maintains a certified drinking water laboratory to assure compliance with all state and federal regulations and is committed to prompt and thorough notification to the consumers if there is any reason for concern about the quality of the drinking water.

Information about your drinking water is available at the City of Flint web page on the Internet at www.cityofflint.com or by calling the Flint Water Plant & Facilities at (810) 787-6537. The Safe Drinking Water Hotline at (800) 426-4791 is a resource for health related questions and water quality issues. General drinking water information can be found on the USEPA web site at www.epa.gov/safewater/.

Water Source

From January 1st through April 30th 2014, The City of Flint purchased drinking water from the Detroit Water & Sewerage Department (DWSD) which operates several drinking water facilities. Following treatment to remove impurities, the water is pumped by DWSD to the Flint Water Plant, where the water is then monitored and distributed throughout the City.

The source water comes from the lower Lake Huron watershed. The watershed includes numerous short, seasonal streams that drain to Lake Huron. The Michigan Department of Environmental Quality in partnership with the U.S. Geological Survey, the Detroit Water & Sewerage Department, and the Michigan Public Health Institute performed a source water assessment in 2004 to determine the susceptibility of potential contamination. The susceptibility rating is a seven-tiered scale ranging from "very low" to "very high" based primarily on geologic sensitivity, water chemistry, and contaminant sources. The Lake Huron source water intake is categorized as having a moderately low susceptibility to potential contaminant sources. The Lake Huron water treatment plant has historically provided satisfactory treatment of this source water to meet drinking water standards. If you would like to know more information or a complete copy of the report, contact the City of Flint Water Plant at (810) 787-6537.

General Information

In order to ensure that tap water is safe to drink, the EPA prescribes regulations, which limit the amount of certain contaminants in water provided by the public water systems. The Food and Drug Administration (FDA) regulations establish limits for contaminants in bottled water, which must provide the same protection for public health. Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the EPA's Safe Drinking Water Hotline (800-426-4791).

The sources of drinking water (both tap water and bottled water) include rivers, lakes, streams, ponds, reservoirs, springs, and wells. As water travels over the surface of the land or through the ground, it dissolves naturally occurring minerals and, in some cases, radioactive material, and can pick up substances resulting from the presence of animals or from human activity. Contaminants that may be present in source water include:

- **Microbial contaminants;** such as viruses and bacteria, which may come from sewage treatment plants, septic systems, agricultural livestock operations, and wildlife.
- **Inorganic contaminants;** such as salts and metals, which can be naturally-occurring or result from urban storm water runoff, industrial or domestic wastewater discharges, oil and gas production, mining, or farming.
- **Pesticides and herbicides;** which may come from a variety of sources such as agriculture, urban storm water runoff, and residential uses.
- **Organic chemical contaminants;** including synthetic and volatile organic chemicals, which are by-products of industrial processes and petroleum production, and can also come from gas stations, urban storm water runoff, and septic systems.
- **Radioactive contaminants;** which can be naturally occurring or be the result of oil and gas production and mining activities.

Some people may be more vulnerable to contaminants in drinking water than the general population. Immuno-comprised persons such as persons with cancer undergoing chemotherapy, persons who have undergone organ transplants, people with HIV/AIDS or other immune system disorders, some elderly, and infants can be particularly at risk from infections. These people should seek advice about drinking water from their health care providers. EPA/CDC guidelines on appropriate means to lessen the risk of infection by Cryptosporidium and other microbial contaminants are available from the Safe Drinking Water Hotline (1-800-426-4791).

If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Infants and young children are typically more vulnerable to lead in drinking water than the general population. It is possible that the lead levels at your hoe may be higher than at other homes in the community as a result of materials used in your home's plumbing Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. The City of Flint Department of Utilities is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. If you are concerned about elevated lead levels in your home's water, you can minimize your potential exposure to lead in your water by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at http://www.epa.gov/safewater/lead.

Lake Huron Water Treatment Plant

2014 Regulated Detected Contaminants Tables

Regulated Contaminant	Test Date	Unit	Health Goal MCLG	Allowed Level MCL	Highest Level Detected	Range of Detection	Violation yes/no	Major Sources in Drinking Water
Inorganic Chemicals – Monitoring at the Plant Finished Water Tap								
Fluoride	5/13/14	ppm	4	4	0.59	n/a	No	Erosion of natural deposits; Water additive, which promotes strong teeth; Discharge from fertilizer and aluminum factories.
Nitrate	5/13/14	ppm	10	10	0.31	n/a	No	Runoff from fertilizer use; Leaching from septic tanks, sewage; Erosion of natural deposits.
Disinfection By-Products – Monitoring in Distribution System Stage 2 Disinfection By-Products								
Regulated Contaminant	**Test Date**	**Unit**	**Health Goal MCLG**	**Allowed Level MCL**	**Highest LRAA**	**Range of Detection**	**Violation yes/no**	**Major Sources in Drinking Water**
Total Trihalomethanes (TTHM)	2014	ppb	n/a	80	33.0	10.0 - 48.5	No	By-product of drinking water chlorination
Haloacetic Acids (HAA5)	2014	ppb	n/a	60	15.8	8.0 – 19.0	No	By-product of drinking water disinfection
Disinfectant Residuals Monitoring in DWSD Distribution System								
Regulated Contaminant	**Test Date**	**Unit**	**Health Goal MRDGL**	**Allowed Level MRDL**	**Highest RAA**	**Range of Detection**	**Violation yes/no**	**Major Sources in Drinking Water**
Total Chlorine Residual	Jan-Dec 2014	ppm	4	4	0.82	0.64-0.94	No	Water additive used to control microbes
Regulated Contaminant	**Treatment Technique**							**Typical Source of Contaminant**
Total Organic Carbon (ppm)	The Total Organic Carbon (TOC) removal ratio is calculated as the ratio between the actual TOC removal and the TOC removal requirements. The TOC was measured each month and because the level was low, there is no requirement for TOC removal.							Erosion of natural deposits

2014 Turbidity – Monitored every 4 hours at Plant Finished Water Tap			
Highest Single Measurement Cannot exceed 1 NTU	**Lowest Monthly % of Samples Meeting Turbidity Limit of 0.3 NTU (minimum 95%)**	**Violation yes/no**	**Major Sources in Drinking Water**
0.19 NTU	100%	No	Soil Runoff
Turbidity is a measure of the cloudiness of water. We monitor it because it is a good indicator of the effectiveness of our filtration system.			

2014 Microbiological Contaminants – Monthly Monitoring in Distribution System					
Regulated Contaminant	**MCLG**	**MCL**	**Highest Number Detected**	**Violation yes/no**	**Major Sources in Drinking Water**
Total Coliform Bacteria	0	Presence of Coliform bacteria > 5% of monthly samples	0	No	Naturally present in the environment.
E.coli Bacteria	0	A routine sample and a repeat sample are total coliform positive, and one is also fecal or E. coli positive.	0	No	Human waste and animal fecal waste.

2011 Lead and Copper Monitoring at Customers' Tap								
Regulated Contaminant	**Test Date**	**Unit**	**Health Goal MCLG**	**Action Level AL**	**90th Percentile Value***	**Number of Samples Over AL**	**Violation yes/no**	**Major Sources in Drinking Water**
Lead	2011	ppb	0	15	< 2.0	0	No	Corrosion of household plumbing system; Erosion of natural deposits.
Copper	2011	ppm	1.3	1.3	0.10	0	No	Corrosion of household plumbing system; Erosion of natural deposits; Leaching from wood preservatives.

*The 90th percentile value means 90 percent of the homes tested have lead and copper levels below the given 90th percentile value. If the 90th percentile value is above the AL additional requirements must be met.

2014 Radionuclides							
Regulated Contaminant	**Test Date**	**Unit**	**Health Goal MCLG**	**Allowed Level MCL**	**Level Detected**	**Violation yes/no**	**Major Sources in Drinking Water**
Combined Radium Radium 226 & 228	5/13/14	pCi/L	0	5	0.86 + or - 0.55	No	Erosion of natural deposits

2014 Special Monitoring

Contaminant	**MCLG**	**MCL**	**Level Detected**	**Source of Contamination**
Sodium (ppm)	**n/a**	**n/a**	**4.78**	Erosion of natural deposits

Collection, sampling result information and table provided by Detroit Water and Sewerage Department (DWSD) Water Quality Division, ML Semegen
City of Flint sample result information provided by the City of Flint Water Plant, M. Glasgow.

2014 Key to the Detected Contaminant Tables		
Symbol	**Abbreviation for**	**Definition/Explanation**
>	Greater than	
AL	Action Level	The concentration of a contaminant, which, if exceeded, triggers treatment or other requirements which a water system must follow.
HAA5	Haloacetic Acids	HAA5 is the total of bromoacetic, chloroacetic, dibromoacetic, dichoroacetic, and trichloroacetic acids. Compliance is based on the total .
LRAA	Locational Running Annual Average	
MCL	Maximum Contaminant Level	The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to the MCLGs as feasible using the best available treatment technology.
MCLG	Maximum Contaminant Level Goal	The level of contaminant in drinking water below which there is no known or expected risk to health.
mg/L	Milligrams per Liter	A milligram = 1/1000 gram 1 milligram per liter is equal to 1ppm
MRDL	Maximum Residual Disinfectant Level	The highest level of disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.
MRDLG	Maximum Residual Disinfectant Level Goal	The level of a drinking water disinfectant below which there is no known or expected risk to health. MRLDG's do not reflect the benefits of the use of disinfectants to control microbial contaminants.
n/a	Not Applicable	
ND	Not Detected	
NTU	Nephelometric Turbidity Units	Measures the cloudiness of water.
pCi/L	Picocuries per Liter	A measure of radioactivity. Picocurie (pCi) means the quantity of radioactive material producing 2.22 nuclear transformations per minute.
ppb	Parts Per Billion (one in one billion)	The ppb is equivalent to micrograms per liter. A microgram = 1/1000 milligram.
ppm	Parts Per Million (one in one million)	The ppm is equivalent to milligrams per liter. A milligram = 1/1000 gram.
RAA	Running Annual Average	
TT	Treatment Technique	A required process intended to reduce the level of a contaminant in drinking water.
TTHM	Total Trihalomethanes	Total Trihalomethanes is the sum of chloroform, bromodichloromethane, dibromoochloromethane and bromoform. Compliance is based on total.

FLINT WATER PLANT

City of Flint
Water Plant & Facilities

2014 Consumers Annual Report on Water Quality

The City of Flint Department of Utilities is dedicated to providing high quality drinking water to the residents of the community. The Consumers Annual Report on Water Quality provides important information about your drinking water. This report includes information about the source of the water, health information, a chart summarizing United States Environmental Protection Agency (USEPA) required testing results, and a table giving explanations of important terms to understand when viewing the test results. The Flint Water Plant & Facilities operates and maintains a certified drinking water laboratory to assure compliance with all state and federal regulations and is committed to prompt and thorough notification to the consumers if there is any reason for concern about the quality of the drinking water.

Information about your drinking water is available at the City of Flint web page on the Internet at www.cityofflint.com or by calling the Flint Water Plant & Facilities at (810) 787-6537. The Safe Drinking Water Hotline at (800) 426-4791 is a resource for health related questions and water quality issues. General drinking water information can be found on the USEPA web site at www.epa.gov/safewater/.

Water Source

From January 1st through April 30th 2014, The City of Flint purchased drinking water from the Detroit Water & Sewerage Department (DWSD) which operates several drinking water facilities. Following treatment to remove impurities, the water is pumped by DWSD to the Flint Water Plant, where the water is then monitored and distributed throughout the City.

The source water comes from the lower Lake Huron watershed. The watershed includes numerous short, seasonal streams that drain to Lake Huron. The Michigan Department of Environmental Quality in partnership with the U.S. Geological Survey, the Detroit Water & Sewerage Department, and the Michigan Public Health Institute performed a source water assessment in 2004 to determine the susceptibility of potential contamination. The susceptibility rating is a seven-tiered scale ranging from "very low" to "very high" based primarily on geologic sensitivity, water chemistry, and contaminant sources. The Lake Huron source water intake is categorized as having a moderately low susceptibility to potential contaminant sources. The Lake Huron water treatment plant has historically provided satisfactory treatment of this source water to meet drinking water standards. If you would like to know more information or a complete copy of the report, contact the City of Flint Water Plant at (810) 787-6537.

General Information

In order to ensure that tap water is safe to drink, the EPA prescribes regulations, which limit the amount of certain contaminants in water provided by the public water systems. The Food and Drug Administration (FDA) regulations establish limits for contaminants in bottled water, which must provide the same protection for public health. Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the EPA's Safe Drinking Water Hotline (800-426-4791).

The sources of drinking water (both tap water and bottled water) include rivers, lakes, streams, ponds, reservoirs, springs, and wells. As water travels over the surface of the land or through the ground, it dissolves naturally occurring minerals and, in some cases, radioactive material, and can pick up substances resulting from the presence of animals or from human activity. Contaminants that may be present in source water include:

- **Microbial contaminants;** such as viruses and bacteria, which may come from sewage treatment plants, septic systems, agricultural livestock operations, and wildlife.
- **Inorganic contaminants;** such as salts and metals, which can be naturally-occurring or result from urban storm water runoff, industrial or domestic wastewater discharges, oil and gas production, mining, or farming.
- **Pesticides and herbicides;** which may come from a variety of sources such as agriculture, urban storm water runoff, and residential uses.
- **Organic chemical contaminants;** including synthetic and volatile organic chemicals, which are by-products of industrial processes and petroleum production, and can also come from gas stations, urban storm water runoff, and septic systems.
- **Radioactive contaminants;** which can be naturally occurring or be the result of oil and gas production and mining activities.

Some people may be more vulnerable to contaminants in drinking water than the general population. Immuno-comprised persons such as persons with cancer undergoing chemotherapy, persons who have undergone organ transplants, people with HIV/AIDS or other immune system disorders, some elderly, and infants can be particularly at risk from infections. These people should seek advice about drinking water from their health care providers. EPA/CDC guidelines on appropriate means to lessen the risk of infection by Cryptosporidium and other microbial contaminants are available from the Safe Drinking Water Hotline (1-800-426-4791).

If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Infants and young children are typically more vulnerable to lead in drinking water than the general population. It is possible that the lead levels at your hoe may be higher than at other homes in the community as a result of materials used in your home's plumbing Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. The City of Flint Department of Utilities is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. If you are concerned about elevated lead levels in your home's water, you can minimize your potential exposure to lead in your water by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at http://www.epa.gov/safewater/lead.

Lake Huron Water Treatment Plant
2014 Regulated Detected Contaminants Tables

Regulated Contaminant	Test Date	Unit	Health Goal MCLG	Allowed Level MCL	Highest Level Detected	Range of Detection	Violation yes/no	Major Sources in Drinking Water
Inorganic Chemicals – Monitoring at the Plant Finished Water Tap								
Fluoride	5/13/14	ppm	4	4	0.59	n/a	No	Erosion of natural deposits; Water additive, which promotes strong teeth; Discharge from fertilizer and aluminum factories.
Nitrate	5/13/14	ppm	10	10	0.31	n/a	No	Runoff from fertilizer use; Leaching from septic tanks, sewage; Erosion of natural deposits.

Disinfection By-Products – Monitoring in Distribution System Stage 2 Disinfection By-Products								
Regulated Contaminant	**Test Date**	**Unit**	**Health Goal MCLG**	**Allowed Level MCL**	**Highest LRAA**	**Range of Detection**	**Violation yes/no**	**Major Sources in Drinking Water**
Total Trihalomethanes (TTHM)	2014	ppb	n/a	80	33.0	10.0 - 48.5	No	By-product of drinking water chlorination
Haloacetic Acids (HAA5)	2014	ppb	n/a	60	15.8	8.0 – 19.0	No	By-product of drinking water disinfection

Disinfectant Residuals Monitoring in DWSD Distribution System								
Regulated Contaminant	**Test Date**	**Unit**	**Health Goal MRDGL**	**Allowed Level MRDL**	**Highest RAA**	**Range of Detection**	**Violation yes/no**	**Major Sources in Drinking Water**
Total Chlorine Residual	Jan-Dec 2014	ppm	4	4	0.82	0.64-0.94	No	Water additive used to control microbes

Regulated Contaminant	Treatment Technique	Typical Source of Contaminant
Total Organic Carbon (ppm)	The Total Organic Carbon (TOC) removal ratio is calculated as the ratio between the actual TOC removal and the TOC removal requirements. The TOC was measured each month and because the level was low, there is no requirement for TOC removal.	Erosion of natural deposits

2014 Turbidity – Monitored every 4 hours at Plant Finished Water Tap			
Highest Single Measurement Cannot exceed 1 NTU	**Lowest Monthly % of Samples Meeting Turbidity Limit of 0.3 NTU (minimum 95%)**	**Violation yes/no**	**Major Sources in Drinking Water**
0.19 NTU	100%	No	Soil Runoff
Turbidity is a measure of the cloudiness of water. We monitor it because it is a good indicator of the effectiveness of our filtration system.			

2014 Microbiological Contaminants – Monthly Monitoring in Distribution System					
Regulated Contaminant	**MCLG**	**MCL**	**Highest Number Detected**	**Violation yes/no**	**Major Sources in Drinking Water**
Total Coliform Bacteria	0	Presence of Coliform bacteria > 5% of monthly samples	0	No	Naturally present in the environment.
E.coli Bacteria	0	A routine sample and a repeat sample are total coliform positive, and one is also fecal or E. coli positive.	0	No	Human waste and animal fecal waste.

2011 Lead and Copper Monitoring at Customers' Tap								
Regulated Contaminant	**Test Date**	**Unit**	**Health Goal MCLG**	**Action Level AL**	**90th Percentile Value***	**Number of Samples Over AL**	**Violation yes/no**	**Major Sources in Drinking Water**
Lead	2011	ppb	0	15	< 2.0	0	No	Corrosion of household plumbing system; Erosion of natural deposits.
Copper	2011	ppm	1.3	1.3	0.10	0	No	Corrosion of household plumbing system; Erosion of natural deposits; Leaching from wood preservatives.

*The 90th percentile value means 90 percent of the homes tested have lead and copper levels below the given 90th percentile value. If the 90th percentile value is above the AL additional requirements must be met.

2014 Radionuclides							
Regulated Contaminant	**Test Date**	**Unit**	**Health Goal MCLG**	**Allowed Level MCL**	**Level Detected**	**Violation yes/no**	**Major Sources in Drinking Water**
Combined Radium Radium 226 & 228	5/13/14	pCi/L	0	5	0.86 + or - 0.55	No	Erosion of natural deposits

2014 Special Monitoring

Contaminant	MCLG	MCL	Level Detected	Source of Contamination
Sodium (ppm)	**n/a**	**n/a**	**4.78**	Erosion of natural deposits

Collection, sampling result information and table provided by Detroit Water and Sewerage Department (DWSD) Water Quality Division, ML Semegen
City of Flint sample result information provided by the City of Flint Water Plant, M. Glasgow.

2014 Key to the Detected Contaminant Tables		
Symbol	**Abbreviation for**	**Definition/Explanation**
>	Greater than	
AL	Action Level	The concentration of a contaminant, which, if exceeded, triggers treatment or other requirements which a water system must follow.
HAA5	Haloacetic Acids	HAA5 is the total of bromoacetic, chloroacetic, dibromoacetic, dichoroacetic, and trichloroacetic acids. Compliance is based on the total .
LRAA	Locational Running Annual Average	
MCL	Maximum Contaminant Level	The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to the MCLGs as feasible using the best available treatment technology.
MCLG	Maximum Contaminant Level Goal	The level of contaminant in drinking water below which there is no known or expected risk to health.
mg/L	Milligrams per Liter	A milligram = 1/1000 gram 1 milligram per liter is equal to 1ppm
MRDL	Maximum Residual Disinfectant Level	The highest level of disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.
MRDLG	Maximum Residual Disinfectant Level Goal	The level of a drinking water disinfectant below which there is no known or expected risk to health. MRLDG's do not reflect the benefits of the use of disinfectants to control microbial contaminants.

DEQ Timeline

1/28/2015 - Meeting requested by Hurley Hospital and McLaren hospital with Department of Community Health (now Dept. of Health and Human Services) and Department of Environmental Quality staff concerning Genesee County Health Department response to Legionellosis Investigations.

1/30/2015 DEQ provided DCH staff with City of Flint water system information.

3/17/2015 – DEQ call and email to the City of Flint regarding optimization strategies to help minimize the potential for outbreaks in customer plumbing systems

3/10/2015 – 3/19/2015 – Discussion with Genesee County Health Department regarding information requests Genesee County made to the City of Flint (DEQ shared with DCH on 3/12)

4/8/2015 – Conference call between DCH (DHHS) and DEQ regarding DCH case and epidemiology status update (Prysby and Shekter Smith)

4/9/2015 – 4/10/2015 – DEQ staff attended smart water summit via live stream on Legionella issues

4/14/2015 – Meeting between DCH (DHHS) and DEQ (Prysby, Busch, Philip, Shekter Smith)

4/14/2015 – DEQ call with EPA regarding EPA ORD assistance abilities for City and DCH.

4/24/2015 – DEQ emailed DCH with City of Flint water quality information from sampling and operational monitoring

4/24/2015 – DEQ notified DCH via email of meetings with hospitals scheduled for 4/29/2015

4/29/2015 – DEQ Meetings with the following regarding secondary treatment and premise plumbing
- Hurley Hospital
- McLaren Hospital
- City of Flint Cross Connection Inspection/Plumbing Inspector

5/1/2015 – DEQ emails with information regarding water safety plans and best practices to
- Hurley Hospital
- McLaren Hospital

5/1/2015 – DEQ emails to City of Flint Cross Connection Inspector / Plumbing Inspector with info on identifying customers that should consider development of a Water Safety Plan for their premise plumbing

5/5/2015 – DEQ ODWMA internal meeting to discuss how to proceed regarding secondary treatment

5/12/2015 – Response from the City of Flint with list of customers that may need a Water Safety Plan

6/52015 – 6/8/2015 – Email communications between Genesee County Health Department and DCH regarding epidemiology status update

6/15/2015 – DEQ Meeting with Dept. of Licensing and Regulatory Affairs regarding Secondary Treatment

6/19/2015 – DEQ Letter to Michigan Society for Health Care Engineering and Michigan Health and Hospital Association regarding secondary treatment

7/30/2015 – DEQ Holds Hospital/Health Care Facility Treatment of Water Received from a Public Water Supply Meeting

Legionellosis Questionnaire
Genesee County, 2014-2015

Interviewer Identification

Date of Interview: _____ Interviewer's Name: _____
Health Dept.: _____ Phone Number: _____ E-mail: _____

What was the patient's outcome? ☐ *RECOVERED* ☐ *STILL ILL* ☐ *DIED* ☐ *UNK*

Patient Contact Information

Name: _____ Age: _____ Sex: ☐ M ☐ F
Street address: _____ City: _____
State: _____ Zip: _____ County: _____
Daytime Phone: _____ Evening Phone: _____

Surrogate Contact Information *<List surrogate contact information if patient is too unwell or has died>*

Name: _____
Daytime Phone: _____ Evening Phone: _____
Relationship to Patient: _____

Hello, my name is _____ and I'm calling from _____ (health department). We are investigating a cluster of respiratory illnesses in Genesee County. At this point, the source of these illnesses is still under investigation. We are hoping this interview will provide further information and answers about the illnesses. I'd like to ask you a few questions about your home and your exposures during the 2 weeks before you got sick. You do not have to answer any of the questions, but any assistance you can provide is appreciated. Do you have about 30 minutes to talk? If not now, when would be a good time for me to call back? _____

<If the case is from more than 1 month prior, the following text may be used: >
It might be helpful for you to collect documents such as a calendar, receipts, credit card or bank statements to jog your memory about your activities and where you were in the 2 weeks prior to getting sick. The only information we would ask you to share from these are dates and locations. Would you like me to call you back after you have time to collect these materials? When would be a convenient day and time for me to call you back? _____

I have that your first symptom started on *<insert onset date>* _____. Is this correct?

☐ Yes ☐ No ☐ Not sure

If no, what was the first date you started feeling sick? ___/___/_____

List dates of exposure period: from ___/___/___ *to* ___/___/___ *<The exposure period includes the 2 weeks before the date of illness onset>*

Illness Information

1.) During your illness, did you have any of the following symptoms?

	Check one:		
	YES	NO	UNK
Diagnosis of pneumonia			
Fever If yes, highest temp:			
Chills			
Cough			
Nausea			
Vomiting			
Diarrhea			
Aches or muscle pains			
Chest pain			
Shortness of breath			
Sore throat			
Headaches			
Other symptoms (*specify*):			

Exposure Information

2.) How long have you lived at your current residence? _____

<If they have moved since the listed exposure period, indicate that you are asking about the house they lived in prior to becoming sick>

a.) If you moved after the exposure period/illness, what was your previous residence address? _____

3.) Where did you get your tap (drinking and other household use) water from between ___/___/___ and ___/___/___ ? *<Exposure period from above>*

- ☐ 1. City of Flint Water
- ☐ 2. City of Flint Township Water
- ☐ 3. Other municipal water system
- ☐ 4. Private well
- ☐ 5. Unknown
- ☐ 6. Other _____

4.) During the last year, has the water pressure at your residence changed? ☐ Yes ☐ No ☐ Not Sure

a.) If yes, did the water pressure: ☐ Increase ☐ Decrease

b). If yes, when did the water pressure change occur? _____

5.) During the last year, has the water quality (appearance, taste, smell) at your residence changed?
☐ Yes ☐ No ☐ Not Sure
a.) If yes, please describe the change in the water quality:_____
_____
b). If yes, when did the water quality change occur? _____

6.) Prior to your illness, did you make any recent plumbing changes or repairs at your residence?
☐ Yes ☐ No ☐ Not sure
a.) If yes, please describe the changes/repairs and give the dates the work was done.
_____
_____

7.) Prior to your illness, were there any water main breaks or other water line issues that affected the water at your residence, including boil water advisories? ☐ Yes ☐ No ☐ Not sure
a.) If yes, please describe the water main/line issues or boil water advisories and give the dates they occurred.
_____
_____

I'd like to ask you some questions about what you did during the 2 weeks **before** you got sick.
The time period I'm asking about is between ___/___/___ and ___/___/___.*<Exposure period>*
During this 2 week period, did you:

8.) Work or volunteer, either full or part time? ☐ Yes ☐ No ☐ Not sure
a.) If yes, complete the following table:

Job description	Company	Location	Any exposure to misty water?

9.) Spend any time in a hospital, doctor's office, clinic, or dentist office as a patient, visitor, employee, or volunteer? ☐ Yes ☐ No ☐ Not sure
a.) If yes, check all that apply:

Exposure	Date(s)	Reason for Visit	Name & City of Hospital/ Office/ Clinic	Name of Doctor
Inpatient ☐	Admission_____ Discharge_____			
Outpatient ☐				
Visitor ☐				
Employee ☐				
Volunteer ☐				

10.) Visit, reside, or work in a long term care facility, nursing home, assisted living facility, or senior living facility? ☐Yes ☐No ☐Not sure

a.) If yes, complete the following table:

Exposure	Date(s)	Name & City of Facility
Resident ☐		
Visitor ☐		
Employee ☐		

11.) In the 2 weeks before you before you got sick (___/___/___ to ___/___/___), did you spend any nights away from home (excluding healthcare settings)? ☐Yes ☐No ☐Not sure

a.) If yes, complete the following table: *<prompts: hotel, campground, cabin, cruise, second home, with family, etc.>*

Accommodation Type/Name	Address Street, City, State	Floor/Room No.	Dates of Stay	
			Arrival	Departure

12.) In the 2 weeks before you before you got sick (___/___/___ to ___/___/___), did you visit any of the following community venues?

	Check one:					
Venue	YES	NO	UNK	Date(s)	Name of Venue	Address
Hotel (*without* staying overnight – e.g. dinner, wedding)						
Auditorium						
Barbershop or Hair salon						
Car wash						
Casino						
Church or Place of worship						
Gym or Work out facility						
Grocery store						
Home improvement store						
Spa or Nail salon						
Mall or Department store						
Movie theater						
Other (*specify*)						

13.) In the 2 weeks before you before you got sick (___/___/___ to ___/___/___), did you have exposure to any of the following water sources, either ***at home*** or while ***away from home***?

Exposures ***at home***	Check one: YES	NO	UNK	Dates (s)	Description: Name (or Type)/Location
Shower					
Use a detachable shower head or hose					
Hot tub, whirlpool spa, Jacuzzi tub					
Sat NEAR a working hot tub or whirlpool spa but did not get in					
Steam room or wet sauna					
Humidifier (whole house or portable)					If yes, specify type: If yes, what type of water is used in device? □Bottled □Tap □Other:_____
Respiratory therapy machine (e.g. nebulizer, CPAP, BiPAP, etc.)					If yes, specify type: If yes, what type of water is used in device? □Bottled □Tap □Other:_____
Other (*specify*)					

Exposures ***away from home***	YES	NO	UNK	Dates (s)	Description: Name (or Type)/Location
Shower at gym, work, other location					
Use a detachable shower head or hose					
Hot tub, whirlpool spa, Jacuzzi tub					
Sat NEAR a working hot tub or whirlpool spa but did not get in					
Humidifier (whole house or portable)					If yes, specify type: If yes, what type of water is used in device? □Bottled □Tap □Other:_____
Pool/splash pad/waterpark					
Recreational or cooling misters					
Steam room or wet sauna					
Decorative fountain					
Outdoor watering hose or sprinkler					
Beach, lake, pond, river, creek, etc.					
Other (*specify*)					

MDSS ID _____

Medical History

Now I'm going to ask a few questions about your medical history and health behaviors.

14.) Have you ever been told by a healthcare provider that you had any of the following conditions:

	Check one:			
Condition	YES	NO	UNK	Comments
Chronic kidney disease				
Weakened immune system (due to cancer, chemotherapy, radiation therapy, immunosuppressive meds, HIV, organ transplant, etc.)				
Diabetes				
Chronic lung disease (COPD, emphysema)				
Asthma or chronic bronchitis				
Heart disease or congestive heart failure				
Liver disease				
Other conditions (*specify*)				

15.) Health behaviors:

	Check one:			
	YES	NO	Quantity per day (packs or drinks)	Duration (years)
Are you currently a smoker?				
Are you a former smoker?				
Do you drink alcohol?				

16.) Do you know anyone else with similar symptoms? ☐ Yes ☐ No ☐ Not sure

a.) If yes, complete the following table:

Name	Phone	State of Residence	Details of Shared Exposure

Additional Comments _____

_____

_____

_____

_____

Thank you so much for taking the time to answer these questions. Do you have any questions that I can help answer? If you have any questions or remember any further details later, please contact the _____ (health department) at phone: _____.

Preliminary Stats on Genesee County Legionellosis Investigation,

As of April 7, 2015

Number of lab-confirmed cases of Legionnaires' Disease: 45

Number of Pontiac fever cases: 1 possible

Total number of legionellosis cases: 46

Geographic distribution:

45/46 Genesee Co (27 Flint, 6 Mt. Morris, 4 Burton, 2 Flint Twp, 1 Flushing, 1 Byron, 1 Davison, 1 Linden, 1 Otisville, 1 Vienna Twp)

1/46 Saginaw County (1 Chesaning)

Age range: 26-94 years

Average age (median): 62.2 years (63.5 years)

% Males: 50% (23/46)

Range of illness onset dates (n=45): 6/6/14-3/9/15

Number (%) of deaths: 15.2% (7/46); expect this number will increase as interviews are completed

Number (%) with other underlying comorbidities: TBD

Conference calls with Genesee County: Jan 27; Feb 10, Feb 19, Apr 7, 2015

Conference calls with hospitals: Jan 28, 2015

Date outbreak-specific survey completed and approved: 2/23/15

Number of cases interviewed: 21 completed (45.7%; 82.6% in total attempted/completed)

MDCH: 14 completed / 29 contacted (MDCH had 2 interviewers – now increased to 4)

Genesee: 7 completed / 10

Number (%) of cases hospitalized: 45/46 (97.8%). Number in ICU: 22/45 (48.8%)

Number (%) of cases hospitalized at McLaren: 18/45 (40%)

Number (%) of cases hospitalized at Hurley: 14/45 (31%)

Number (%) of cases hospitalized at Genesys: 6/45 (13.3%)

Number (%) of cases hospitalized at other hospitals outside Flint: 7/45 (15.6%)

Number (%) of cases who had been hospitalized in 2-weeks prior to onset: 20/45 (44.4%)

Number (%) of cases who had been hospitalized in 2-weeks prior to onset at McLaren: 16/45 (35.6%)

Number (%) of cases who had been hospitalized in 2-weeks prior to onset at Hurley: 2/45 (4%)

Number (%) of cases who had been hospitalized in 2-weeks prior to onset at Genesys: 0

Number (%) of cases who had been hospitalized in 2-weeks prior to onset at other hospitals: unknown

Number (%) of cases who had a short-term visit to a hospital in 2-weeks prior to onset:

Number (%) of cases who had a short-term visit to McLaren facility in 2-weeks prior to onset: 5/45 (11.1%)

Number (%) of cases who had a short-term visit to Hurley facility in 2-weeks prior to onset: 1/45 (2%)

Number (%) of cases who had a short-term visit to Genesys facility in 2-weeks prior to onset: 0

Number (%) of cases who had been hospitalized or who had a short-term visit to a hospital facility in 2-weeks prior to onset:

Number (%) of cases who had been hospitalized or who had a short-term visit to a McLaren facility in 2-weeks prior to onset: 21/45 (46.7%)

Number (%) of cases who had been hospitalized or who had a short-term visit to a Hurley facility in 2-weeks prior to onset: 3/45 (6.7%)

Number (%) of cases who had been hospitalized or who had a short-term visit to a Genesys facility in 2-weeks prior to onset: 0

Number (%) of cases who work outside the home: 8/46 (17.4%) [min of 72% at home]

Number (%) of cases who are retired: 20 (43.5%)

Number (%) of cases who are unemployed: 7/46 (15.2%)

Number (%) of cases who are disabled: 6/46 (13%)

Number (%) of cases whose occupation status is unknown: 5/46 (10%)

Genesee County Health Department

Mark Valacak, M.P.H., Health Officer
Gary K. Johnson, M.D., M.P.H., Medical Director

January 27, 2015

FOIA Coordinator, City of Flint
1101 S. Saginaw Street, 3rd floor
Flint, MI 48502

RE: Flint Water Plant Information Request

Dear FOIA Coordinator,

Under provisions of the Michigan Freedom of Information Act (MCLA 15.231 et seq; MSA 4.1801 (1) et seq) please provide copies of the following:

Provide specific water testing locations and laboratory results within the City of Flint public water system for Coliform, E-coli, Heterotrophic Bacteria and Trihalomethanes from January 1, 2010 to January 27, 2015. Provide any additional water testing that has been conducted for identifying potential public health risks. Include any available mapping of the water testing areas.

Provide a map delineating the boundaries of the City of Flint water distribution system. Include any changes to the boundaries, along with corresponding dates from January 1, 2014 to January 27, 2015.

Provide a map or list of locations, detailing dead ends, pooling, low pressure and any additional areas of concern within the City of Flint water distribution system. Include any modifications to the water distribution system addressing concerns, along with corresponding dates from January 1, 2014 to January 27, 2015.

If you determine that any of the requested information is exempt from disclosure, please detail what is being withheld and cite the exemption under FOIA. I anticipate the request being filled within five working days of receipt of this letter, as provided under FOIA. Please contact me at (810) 257-3618 if there are fees associated to comply with this request.

Sincerely,

Jim Henry

Importance: High

Here is the reply from DCH:
Hi Julia,

We have the capacity to look for Legionella in water, but we only perform the test when it is a part of an epidemiologic investigation. If the health department contacts our Bureau of Epidemiology and they confirm the human case and want to look for a source, we can test. They may want to contact Shannon Johnson in the Bureau of Epi. Her number is 335-9597.

Hi Richard,

We do not do Legionella testing. Julie is in the process of finding out from DCH if they can do it. She will provide that information once it becomes available.

George or Julia,

Are you prepared for performing analyses for legionella in water? If so, would you please answer the questions below. If not, do you know if the DCH lab is capable of doing so? Can you provide a contact. Liane suggest I copy Linda Dykema, so perhaps she can answer for community health, particularly if there are any labs in Southwest Michigan that may be relied upon if the state is unable to do so.

3-28-14
Julia,
Summary at 10:05am Mick McGuire of the Van Buren Cass County District Health Dept contacted this office.

- Per Mick McGuire, Van Buren Cass County District Health Dept, there is a man who was diagnosed with Legionnaires Disease either yesterday, or today.
- It is not known which location this "man" may have worked at: Either Cass County or Berrien County.
- The VBCCDHD is investigating IF the "man" works at a previously "inactive" Type 2 public water supply in Cass County.

Preliminary Stats on Genesee County Legionellosis Investigation,

As of April 7, 2015

Number of lab-confirmed cases of Legionnaires' Disease: 45

Number of Pontiac fever cases: 1 possible

Total number of legionellosis cases: 46

Geographic distribution:

45/46 Genesee Co (27 Flint, 6 Mt. Morris, 4 Burton, 2 Flint Twp, 1 Flushing, 1 Byron, 1 Davison, 1 Linden, 1 Otisville, 1 Vienna Twp)

Department of Utilities

FLINT WATER PLANT

Memorandum

To: Water Plant Personnel

From: Mike Glasgow
Utilities Administrator

Date: October, 22 2015

Subject: **Laboratory testing requirements for current water supply**

Due to the recent change in water supply, the drinking water testing for the water plant laboratory personnel has been adjusted. The testing has been arranged to reflect what was conducted in years prior to operation of the treatment plant from the river. There are a few additional items that have been included, and this schedule may be adjusted as necessary.

AM & PM PLANT RUN:

- Collect & analyze samples for chlorine residual and Coliform Bacteria in the morning and afternoon (at least 4 hours apart) from the following sites on plant grounds:
  Control Station # 2, Dort Well, Pump Station # 4, & Lab Tap

LAB TAP TESTING:

- Collect & analyze lab tap samples once daily for pH, fluoride, total hardness, alkalinity, non-carbonate hardness, calcium, magnesium, total phosphate, temperature and chloride.
- Collect & analyze 3 samples daily (at least 3 hours apart) for Turbidity.
- Collect & analyze 1 sample weekly for Heterotrophic bacteria.

DISTRIBUTION SAMPLING:

- Collect & analyze samples from the 10 distribution sites at least twice weekly for chlorine residual and coliform bacteria. A total of at 100 samples must be collected and analyzed each month, so in total, at least 10 sampling events should take place each month.
- Once weekly also test each distribution site for fluoride, total phosphate, and Heterotrophic bacteria.
- Once quarterly perform Water Quality Parameters (WQM) from the 25 distribution sites. Total phosphate will be a new addition to all the other parameters tested.
- Once quarterly collect Disinfection Byproduct samples (DBP) from 8 sites according to the current DBP schedule. Next sampling will take place the 3rd full week of November.
- Lead & copper sampling will be on going throughout the rest of the year, a detailed plan will be completed soon.

RIVER SAMPLING:

- When time permits, a river sample should be collected once weekly and analyzed for coliform bacteria, pH, fluoride, total hardness, alkalinity, non-carbonate hardness, calcium, magnesium, temperature, turbidity, and chloride.

From: Natasha L. Henderson, City Administrator

cc: President Freeman and Councilmembers

Date: October 20, 2015

Re: Water Filtration Plant and Water Distribution Internal Review

---

Water Filtration Plant and Water Distribution Systems Overview

The City of Flint's water filtration plant and distribution system have experienced many challenges over the past two years and it is of grave concern that we reflect upon the decisions that have been made and understand how we will proceed in the future. First, and foremost the City will conduct an internal review of the steps that were taken in 2013 when the agreement with Karegnondi Water Authority (KWA) was signed.

In the wake of recent water concerns, I have developed a proactive and comprehensive plan showing the City's commitment to deliver high quality water, address its aging infrastructure, and maintain a qualified staff. I am outlining a series of steps that the city will take to not only ensure that these goals are met but a plan that is designed to start rebuilding community trust through action and transparency.

In addition, with the assistance of the EPA Task Force, Michigan Department of Environmental Quality, and Safe Drinking Water Technical Advisory Committee, the following steps are meant to go into effect as quickly as possible with all goals being accomplished by the time KWA begins delivering raw water.

- Independent review
- Processes & Testing
- Training

- Technology
- Communication
- Lead Lines
- Capital Improvements

Independent Review

We will seek to commission an independent source to review the technical and operational steps that occurred from the time the City signed on to the KWA to present. This is meant to internally perform an after action review in order to clearly assess the decisions that were made. My expectation is that we will hire out-side legal counsel to lead this internal review. I believe it is imperative that the City has all information that has led the City to the water quality issues that have arisen.

Internal Processes & Testing

We understand that EPA standards are the minimum requirements that utility systems are required to meet, the City will establish and move forward with higher standards and goals than those set by regulators. As these new standards are set, they will be published with a plan on how to obtain each goal complete with expected timeframes. The following are the first set of goals that have been set by the City that exceed the regulatory requirements.

Regulatory Requirements	City Goals
(1) F-1 Licenced Personnel	(2) F-1 Licenced Personnel
(1) S-1 Licensed Personnel	(2) S-1 Licensed Personnel
100 TTHM Samples per Month	120 TTHM Samples per Month
100 Lead/Copper Volunteer Samples / yr.	300 Lead/Copper Volunteer Samples / yr.
Annual Water Quality Report	Quarterly Water Report

Training

We will encourage all utility employees to become members of the American Water Works Association (AWWA) which is the largest nonprofit, scientific and educational association dedicated to managing and treating water. The AWWA offers continual training opportunities and the City will develop an internal training regimen that employees must adhere to. The goal is to continue to develop each employee which promotes a long term succession plan.

Technology

The addition of enhanced Supervisory Control and Data Acquisition (SCADA) will make sure that the system is running with the industries most updated technology and running as efficient as possible. The SCADA adds automation to the Water Plant thereby reducing the need for as much manual intervention. The City will also maintain Safe Drinking Water Technical Advisory Committee with more consistent meetings.

Enhanced Communication

We recognize that one of the key features of a Utility is the public communication with honest and candid information. We will increase the way we send information to people and the frequency that our communication is available. The following are first steps in that direction.

- Monitors around City Hall that display information about the water system

- Direct emails to individuals and neighborhood groups informing people where work is occurring
- Door hangers for field workers to distribute alerting people when water may be off or discolored
- A website page and GIS map dedicated to water events
- Quarterly Water reports that are directly mailed to users
- More frequent press releases that provide information relating to infrastructure concerns
- Immediate notification using all of the above media if a violation occurs
- An answering service so that every call is answered in a timely manor

Lead Service Lines

Every effort will be made to ensure a program will is in place to address the long-term goal of replacing all lead service lines. The program is expected to address the location of all City owned lead service lines and look to provide an opportunity for homeowners to receive a grant in order to have their service line changed at the same time as the city is changing its lines. This coordinated program will look to utilize funds from multiple avenues to support City residents, such as:

- CDBG Funds
- DWRF revolving loan funding
- Grant funding

Capital Improvement Plan

The City will continue to modify its 5-year CIP annually to make sure that we are always addressing the most critical issues facing the City. Another rate study will help set the correct rate for the system and determine the proper allocation to address concerns. The Water Reliability Study will continue to highlight the critical needs and will continue to be updated every two years.

As City Administrator, my goal is to ensure all of the necessary steps are in place prior to the implementation of KWA delivering water to the City. All of these initiatives will be inserted into the Utilities strategic plan and tracked regularly by staff, myself, and reported to the DPW Committee to ensure accountability.

RICK SNYDER
GOVERNOR

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

DAN WYANT
DIRECTOR

March 5, 2015

Mr. Brent Wright, Operations Supervisor
City Of Flint - DPW
Flint Water Plant
4500 North Dort Highway
Flint, Michigan 48505

WSSN: 02310

Dear Mr. Wright:

SUBJECT: Violation Notice (VN) – Maximum Contaminant Level for Total Trihalomethanes (TTHM)
Operational Evaluation – Total Trihalomethanes
1st Quarter 2015 Monitoring Period

The Department of Environmental Quality (DEQ), Office of Drinking Water and Municipal Assistance (ODWMA), records show that the city of Flint (City) is in violation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399); R 325.10610, *Maximum contaminant levels for disinfection byproducts (MCLs)*, of the 1979 Administrative Code.

In accordance with R 325.10610, *MCL*s, of the 1979 Administrative Code, the MCL for disinfection byproduct TTHM is 0.080 milligrams per liter (mg/L) as a Locational Running Annual Average (LRAA) at each monitoring location. As listed in the table below, our records show that the City's highest TTHM locational running annual average (LRAA), based on the last four quarters, ending February 28, 2015, is 0.105 mg/L which exceeds the standard, and that two of the eight sample site locations exceed the standard of 0.080 mg/L.

Further, in accordance with R 325.10719l, *Disinfection byproducts: operational evaluation levels*, of the 1979 Administrative Code, when an operational evaluation level (OEL) at a monitoring location for TTHM exceeds 0.080 mg/L, a supply shall conduct an operational evaluation and submit a written report of the evaluation to the DEQ not later than 90 days after being notified of the analytical result that causes the supply to exceed the operational evaluation level. As listed in the table below, our records show that the TTHM OELs for the City exceed 0.080 mg/L at one of the City's eight sample site locations.

TTHM Results (mg/L)						
	5/21/14	8/21/14	11/20/14	2/17/15	LRAA	OEL
DBP1 McDonalds 3719 Davison	**0.162**	**0.145**	0.059	0.0162	**0.096**	0.059
DBP2 Liquor Palace 3302 S. Dort Highway	**0.112**	**0.127**	0.033	0.0168	0.072	0.049
DBP3 North Flint Auto 6204 N. Saginaw St.	**0.097**	**0.118**	0.041	0.0149	0.068	0.047
DBP4 University Market 2501 Flushing Road	**0.106**	**0.196**	**0.094**	0.0245	**0.105**	**0.085**
DBP5 Taco Bell 3606 Corunna Road	0.079	**0.181**	0.034	0.0151	0.078	0.063
DBP6 Rite-Aid Pharmacy 5018 Clio Road	**0.088**	**0.144**	0.054	0.0192	0.076	0.059
DBP7 Salem Housing 3216 MLK Boulevard	**0.082**	**0.112**	0.050	0.0285	0.068	0.055
DBP8 BP Gas Station 822 S. Dort Highway	0.075	**0.112**	0.036	0.0199	0.061	0.047

Our investigation consisted of a review of ODWMA files for laboratory reports received for compliance monitoring. Our investigation is considered complete. This violation began on March 1, 2015, and will continue until TTHM LRAA is below the MCL at all sample sites.

We are encouraged by the results from the most recent round of compliance samples collected on February 17, 2015, which now show individual TTHM levels at less than half of the 0.080 mg/L standard at all locations throughout the City's system. Operational Evaluation Reports from December 2014, and February 2015, have identified possible causes and corrective measures for the previous elevated TTHM levels which we encourage the City to continue implementing. These modifications have likely contributed in part to the reduction in TTHM levels reported in the most recent quarter, and suggest the City may be able to achieve compliance with the TTHM standard at all sites by continuing these efforts.

Our office is currently reviewing the Operational Evaluation Report dated February 27, 2015, and will provide the City and their consultant with comments, as needed, to help address this MCL violation.

Water systems that exceed the OEL must complete and submit an Operational Evaluation in accordance with Administrative Rule 719l (R 325.10719l) within 90 days of being notified of the violation. **An updated Operational Evaluation report, which incorporates the most recent sample results, must now be completed and received by our office by no later than Friday, May 29, 2015.**

If you have any other factual information you would like us to consider regarding the violation identified in this VN, please provide them in a written response by March 19, 2015.

Administrative rule R 325.10403 of Act 399 requires that suppliers provide public notice (PN) as soon as practical, but no later than thirty (30) days after the supplier learns of this type of violation, by mail or direct delivery **and** by any other means reasonably calculated to reach customers not normally reached by mail. Enclosed is a sample PN which contains the minimum required language. The City is encouraged to include additional information regarding its response efforts to this violation. **Please notify your consumers by April 1, 2015, and send us a signed and dated copy of the notice that you issued within ten (10) days of distributing the public notice**. This violation must also be included in your 2015 Consumer Confidence Report, due by July 1, 2016. The PN must be repeated every quarter until you no longer exceed the TTHM standard. Failure to issue a PN for this violation will result in a fine of at least $1,000 per event, with a maximum of $5,000 per violation.

We anticipate and appreciate your continued cooperation in resolving this matter. If you have any questions regarding this VN, please contact us at the numbers below; at prysbym@michigan.gov; or rosenthala@michigan.gov; or at DEQ, P.O. Box 30242, Lansing, Michigan 48909-7742.

IMPORTANT INFORMATION ABOUT YOUR DRINKING WATER

City of Flint Did Not Meet Treatment Requirements

Our water system recently violated a drinking water standard. Although this incident was not an emergency, as our customers, you have a right to know what happened and what we are doing to correct this situation.

We routinely monitor for the presence of drinking water contaminants. Samples were collected for total trihalomethanes (TTHM) analysis from eight locations on a quarterly basis (May 21, August 21, November 20 of 2014, and February 17, 2015). The average of the results at **ANY** of the eight locations must not exceed the maximum contaminant level (MCL) for TTHMs, otherwise our water system exceeds the MCL. The standard for TTHMs is 80 micro grams per liter (µg/L). The location reporting the highest TTHM level was 105 ug/L; thus, our water system exceeds the TTHM MCL.

What should I do?

- There is nothing you need to do unless you have a severely compromised immune system, have an infant, or are elderly. These people may be at increased risk and should seek advice about drinking water from their health care providers.
- You do not need to boil your water or take other corrective actions. If a situation arises where the water is no longer safe to drink, you will be notified within 24 hours.

What does this mean?

This is not an emergency. If it had been an emergency, you would have been notified within 24 hours.

People who drink water containing trihalomethanes in excess of the MCL over many years may experience problems with their liver, kidneys, or central nervous system, and may have an increased risk of getting cancer.

What is being done?

We are currently working on solutions to correct the problem. We anticipate resolving the problem in 2015. Our most recent individual sample results were all less than half the 80 µg/L standard, however since compliance is calculated using a locational running annual average (LRAA) of the most recent four quarters, we are still out of compliance with the MCL at two of eight locations.

For more information, please contact Mr. Brent Wright at 517-787-6537, or the Flint Water Plant at 4500 North Dort Highway, Flint, Michigan 48505.

Please share this information with all the other people who drink this water, especially those who may not have received this notice directly (for example, people in apartments, nursing homes, schools, and businesses). You can do this by posting this notice in a public place or distributing copies by hand or mail.

This notice is being sent to you by the City of Flint.

CERTIFICATION: WSSN: 02310

I certify that this water supply has fully complied with the public notification requirements in the Michigan Safe Drinking Water Act, 1976 PA 399, as amended, and the administrative rules.

Signature	Title	Date Distributed

Reminder to water supplier: This notice/certification must be sent to the Department of Environmental Quality.

Instructions for Stage 2 DBPR TTHM or HAA5 MCL Violation Notice – Template 2-19

Template on Reverse

If your system's locational running annual average for Total Trihalomethanes (TTHM) exceeds the MCL of 0.080 mg/L or the locational running annual average for Haloacetic Acid 5 (HAA5) exceeds the MCL of 0.060 mg/L at one or more sampling locations, you must provide public notice to persons served as soon as practical but within 30 days after you learn of the violation [40 CFR 141.203(b)]. You must issue a repeat notice every three months for as long as the violation persists.

Community systems must use one of the following methods [40 CFR 141.203(c)]:

- Hand or direct delivery
- Mail, as a separate notice or included with the bill

Noncommunity systems must use one of the following methods [40 CFR 141.203(c)]:

- Posting in conspicuous locations
- Hand delivery
- Mail

In addition, both community and noncommunity systems must use *another* method reasonably calculated to reach others if they would not be reached by the first method [40 CFR 141.203(c)]. Such methods could include newspapers, e-mail, or delivery to community organizations. If you mail, post, or hand deliver, print your notice on your system's letterhead, if available.

The notice on the reverse is appropriate for mailing, posting, or hand delivery. If you modify this notice, you must still include all required PN elements from 40 CFR 141.205(a) and leave the mandatory language unchanged (see below).

Mandatory Language

Mandatory language on health effects (from Appendix B to Subpart Q) must be included as written (with blanks filled in) and is presented in this notice in italics and with an asterisk on either end.

You must also include standard language to encourage the distribution of the public notice to all persons served, where applicable [40 CFR 141.205(d)]. This language is also presented in this notice in italics and with an asterisk on either end.

Corrective Action

In your notice, describe corrective actions you are taking. Listed below is one step commonly taken by water systems with TTHM or HAA5 MCL violations. You can include the following statement, if appropriate, or develop your own text:

- We are working to minimize the formation of [TTHM or HAA5] while ensuring we maintain an adequate level of disinfectant. We have taken additional steps to change disinfectant type/levels, remove natural organic matter, and increased flushing of water lines to determine if our efforts have been effective.

Repeat Notices

For repeat notices, you should state how long the violation has been ongoing and remind consumers of when you sent out any previous notices. If you are making progress, describe it. Alternatively, if funding or other issues are delaying progress, let consumers know.

After Issuing the Notice

Make sure to send your primacy agency a copy of each type of notice and a certification that you have met the public notice requirements within ten days after you issued the notice [40 CFR 141.31(d)].

IMPORTANT INFORMATION ABOUT YOUR DRINKING WATER

[Contaminant, i.e., Total Trihalomethanes (TTHM) or Haloacetic Acid 5 (HAA5)] MCL Violation at [System]

Our water system recently violated a drinking water standard. Although this incident was not an emergency, as our customers, you have a right to know what happened and what we did (are doing) to correct this situation.

We routinely monitor for the presence of drinking water contaminants. Testing results from [provide date range] show that our system exceeds the standard, or maximum contaminant level (MCL), for [TTHM/HAA5]. The standard for [TTHM/HAA5] is [MCL]. It is determined by averaging all the samples collected at each sampling location for the past 12 months. The level of [TTHM/HAA5] averaged at one of our system's locations for [provide date range] was [level].

What should I do?

- There is nothing you need to do. You do not need to boil your water or take other corrective actions. If a situation arises where the water is no longer safe to drink, you will be notified within 24 hours.
- If you have a severely compromised immune system, have an infant, are pregnant, or are elderly, you may be at increased risk and should seek advice from your health care providers about drinking this water.

What does this mean?

This is not an emergency. If it had been an emergency, you would have been notified within 24 hours.
[TTHM are four volatile organic chemicals] [HAA5 are five haloacetic acid compounds] which form when disinfectants react with natural organic matter in the water.

[**People who drink water containing trihalomethanes in excess of the MCL over many years may experience problems with their liver, kidneys, or central nervous system, and may have an increased risk of getting cancer.**] Or

[**People who drink water containing haloacetic acids in excess of the MCL over many years may have an increased risk of getting cancer.**]

What is being done?

[Describe corrective action.] We anticipate resolving the problem within [estimated time frame] (or the problem was resolved on [give date]).

For more information, please contact [name of contact] at [phone number] or [mailing address].

> **Please share this information with all the other people who drink this water, especially those who may not have received this notice directly (for example, people in apartments, nursing homes, schools, and businesses). You can do this by posting this notice in a public place or distributing copies by hand or mail.***

Re: Term Agreement
Genesee County Drain Commissioner, County Agency

Dear Director McCormick:

We have received and reviewed your letter dated December 12, 2014. As stated in your letter, DWSD and GCDC have been working towards a mutually agreeable solution to a situation that is very unique. In essence, GCDC and DWSD are negotiating toward a short-term, full service contract and a long-term emergency service contract. DWSD currently does not have any contract like this, so there have been many details to work out during our negotiations. There remain two (2) issues that need to be resolved: the cost versus the benefit of the emergency service and the fixed fees that need to be paid during the full service period. During our last conversation with representatives of your office, the later issue may be resolved. With that said, GCDC has committed to negotiating with DWSD to try and reach a mutually acceptable contract for short-term, full service and long-term emergency water supply.

I think it is beneficial to review the time line of events that have transpired.

December 20, 1965	The City of Flint and City of DWSD signed a 35 year contract, which expired on December 31, 2000. The contract continued on a year to year basis thereafter with a one year termination notice provision. A key item in this contract was that DWSD gave franchise rights to the City of Flint for all of Genesee County. As a result, Genesee County could not be a direct customer of DWSD.
April 12, 2013	After the announcement that Flint signed as a constituent member of the KWA, DWSD sent the City of Flint a notice of termination of the contract to be effective April 2014.
November 2013	DWSD/GCDC/DEQ/State met TO DISCUSS Flint's decision process for deciding to go to KWA or stay with DWSD. Also discussed transition if separation was to occur.
April 17, 2014	Contract terminated by DWSD, City of Flint still purchased water, GCDC still purchased water, and Detroit modified its rate to a non-contract customer rate.

April 30, 2014	City of Flint stopped receiving water from DWSD. GCDC closed two valves isolating Flint from the system. Closing the valves was witnessed by personnel of DWSD.
May 1, 2014	GCDC acquired the meter pit then FL-1 now GN-01 from Flint and GCDC became a direct non-contract customer of DWSD.
May and June 2014	GCDC paid its portion of the Flint rate 2013/2014 rate plus a penalty for non-contract status.
July 1, 2014	DWSD and GCDC determined the usage patterns for GCDC.
August 8, 2014	DWSD established a contract rate and a non-contract rate based on GCDC flows and ownership of the meter pit. DWSD billed the new non-contract rate effective July 1, 2014.
November 2014	Negotiations reach an impasse. DWSD says it's going to add additional penalty to GCDC rates.
December 2014	DWSD sends notice that DWSD is going to recommend an additional $1,287,600 to GCDC rates because GCDC is unique.

We have enclosed our rate structure for the past year and the calculation of that rate. Our "current rates" as described in the December 12 letter already includes a penalty and now DWSD in mid-year wants to add an additional penalty.

Back in November of 2013, we all met in Detroit with the Governor regarding water rates and Flint's evaluation of DWSD versus KWA. At that meeting, you spoke of stranded costs and your obligation to recover those costs. Flint signed a 35 year contract. Flint remained a customer for 49 years until DWSD terminated its contract with Flint. There are no stranded costs remaining and if there are, those stranded costs rightfully belong with Flint, who was the contract holder with DWSD. Flint has fulfilled its contractual obligations and upon fulfilling those obligations, DWSD has never identified any stranded costs. Therefore, stranded costs are not at issue in our negotiations and they should not be included in the rate model applied to GCDC.

Since you terminated the contract with Flint, the volume of water has been reduced by 12-18 mgd to the Flint/GCDC area. What new capital investment can you point to that was for the benefit of GCDC? Please provide the legal argument that GCDC might be responsible for these costs. Keep in mind that GCDC has never signed an agreement with DWSD committing it to capital costs for any DWSD projects. GCDC has always made it clear that we would like full service from DWSD through 2016. After that, we were desirous of a mutual aid/backup supply agreement.

The State of Michigan requires a true cost of service in rate making for utilities serving greater than 1% of the State's population. DWSD falls into this category. For your 2013-2014 Budget, you set the rates for all customers by terminating Flint and charging an additional penalty – you received a windfall of revenue from the penalty. For your 2014-2015 Budget, you did not include Flint or GCDC in your rate calculation. The water revenue and penalty paid by GCDC is a windfall. Now mid-year, you are requesting an additional surcharge for the balance of the year – another windfall.

As you stated, we are unique. This uniqueness was identified in August of 2014 when you established a rate for GCDC outside of your rate model. In comparison to your contract customers, GCDC is unique. Contract customers are calculated by the model, even though GCDC rates are calculated by the model, GCDC pays a non-contract penalty as a percentage. This penalty is not paid by contract customers. Additionally, GCDC pays 80% of its rates in fixed fees. Contract customers pay 40% of its rates in fixed fees. Finally, it appears GCDC's rates can be changed arbitrarily at the whim of the Director and Board. Contract customers cannot.

This new proposed rate is vindictive, insulting and illegal. Both Genesee County and the City of Detroit are subdivisions of the State of Michigan. Should these punitive rates be put into effect, we will aggressively pursue all remedies available. With respect to the Governor, we have honored his request to not sue DWSD, but that is a request he can no longer expect us to honor.

Your statement that GCDC is in a fundamentally different position from Flint and other customers of DWSD as GCDC is correct, as GCDC has never been a contractual customer of DWSD. It is important here to recognize that due to the actions of DWSD in giving the franchise rights to the City of Flint for all of Genesee County, it was not possible for GCDC to be a customer. DWSD's actions are the only reason GCDC has never been a contract customer of DWSD. Flint was the only "old contract" customer that had their contract terminated. Why?

If it is the intent of DWSD to recapture capital costs associated with DWSD infrastructure investments, DWSD should have pursued these claims against the City of Flint when DWSD terminated its relationship with Flint. In essence, your argument is that any new customer to your system should be required to pay for prior improvements to the DWSD system even though the improvements were for a different customer of DWSD, the fact remains that the GCDC/Flint area uses 40% less water volume today than 8 months ago when Flint was also purchasing water from DWSD. DWSD has not needed to upgrade its infrastructure, nor has GCDC requested DWSD to do so, to furnish less water to the Genesee County area. Therefore, to establish another new rate for a non-contract customer to recoup capital investment that was never committed to that customer demonstrates clearly that this is a play to force GCDC into a long-term agreement with DWSD or results in a punitive charge.

GCDC and DWSD have been negotiating a short-term/long-term contract. GCDC does not need a backup supply from DWSD. We are willing to consider one if the cost is beneficial to our system. DWSD is the one that is requiring a thirty year agreement not GCDC. When GCDC separates from DWSD, there is significant infrastructure that will be mothballed or abandoned by

DWSD. GCDC has offered to purchase the infrastructure from DWSD. This sale would be beneficial to both systems. These negotiations have been put in jeopardy by your threat to increase our rates unless we meet your demands for a long-term agreement.

Due to the above, GCDC has no choice but to suspend negotiations until this issue is resolved.

On a final note, it is interesting that you sent this letter the day after the Emergency Manager resigned.

Sincerely,

John F. O'Brien, P.E., Director
Division of Water and Waste Services

WATER RATE HISTORY

Flint/GCDC
The consistent way to look at the rate by comparison of the aggregate value when it is a combination of fixed fee and commodity rate.

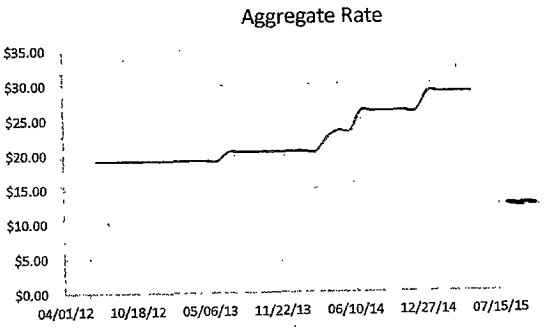
July 2012 – June 2013 (Flint/Genesee)

Fixed Rate	$8,484,000
Commodity	$12.46
Aggregate Rate	$19.11

July 2013 – June 2014 (Flint/Genesee) (Rate through April 17, 2014)

Fixed Rate	$8,856,072
Commodity	$13.01
Aggregate	$20.39

April 17, 2014 – May 2014



Fixed Rate	$9,776,592
Commodity	$14.35
Aggregate	$22.50

May 1 – June 30, 2014

Fixed Rate	$5,080,800
Commodity	$15.18
Aggregate	$23.37

July 2014 – December 2014

Fixed Rate	$13,792,800
Commodity	$3.89
Aggregate	$26.14

January 1, 2015 – June 2016
Proposed

Fixed Rate	$15,451,200
Commodity	$3.89
Aggregate	$28.81

Another way to look at our rates is as the change in percentage:

Rates on Notice of Terminatio	$20.39	
Current Rates	$26.14	28% in 19 months
Proposed Rates	$28.84	42% in 19 months

The cost of the penalty to GCDC since the termination of the DWSD/Flint contract:

Rate on Termination	$20.39
Rate on Non-Contract	$22.50
Difference	$2.11
Cost for April 17 – June 30	$264,910.50
Volume: 185,550	

As stated by DWSD in August of 2014:

Rates Contract 2014 – 2015	$23.16
Rates Non-Contract 2014-201	$26.14
Difference	$2.98
Cost July 1 – December	$923,800
Volume: 310,000	

As stated by DWSD in August of 2014:

Rates Non-Contract	$23.16
Rates Proposed	$28.81
Difference	$5.65
Cost January 1 – June 30, 201	$1,751,500
Volume: 310,000 (estimated)	

Current total:	$1,888,710.50
Projected total: (Same rate)	$2,112,510.50
Projected total: (New rate)	$2,940,210.50

FYI RB/DM/EC/DS JW/VB

CITY OF DETROIT
WATER AND SEWERAGE DEPARTMENT
OFFICE OF THE DIRECTOR

735 RANDOLPH STREET
DETROIT, MICHIGAN 48226-2830
WWW.DETROITMI.GOV

January 12, 2015

Mr. Darnell Earley, Emergency Manager
Mr. Dayne Walling, Mayor
City of Flint
1101 S. Saginaw Street
Flint, Michigan 48502

Dear Messrs. Earley and Walling:

Regarding: Re-establishing Detroit Water and Sewerage Department Water Service

I was recently referred to a report in MLive in which there was reference to the City of Flint (City) potentially re-visiting its decision to utilize Flint River water as a water source prior to the completion of the KWA pipeline. Within that report, there appeared to be some incorrect assumptions about the cost of water service from the Detroit Water and Sewerage Department (DWSD). I write to you today to express the willingness of DWSD to resume delivery of drinking water to the City and its residents. We have monitored the water quality issues that have troubled the City since May, 2014, and understand that many of the difficulties stem from the limited access to source water. Please know that DWSD is ready, willing and able to resume service to the City if you so desire.

If the City is interested in a long term arrangement with DWSD, with this goal in mind, we offer that the City can immediately reconnect to the DWSD system at no additional charge to the City and at the same "expired contract" rate that the City was paying in April, 2014, modified to reflect the 4% increase experienced by all other wholesale customers in July, 2014. The resulting rate structure is a fixed monthly rate of $846,700 and a commodity rate of $14.92/Mcf. In order to facilitate contract negotiations, DWSD is willing to extend this rate to the City (and to Genesee County as the City's partner and former customer) until June 30, 2015.

We at DWSD take very seriously the matter of drinking water quality, and we are as concerned as you must be by the continued quality issues faced by the City. We are confident that DWSD can provide you with a solution for reliable, safe, high quality water on an expeditious timeline. Please contact me directly at (313) 224-4701 if you wish to discuss this offer further.

Sincerely yours,

Sue F. McCormick
Director

Detroit offers Flint 'long-term' deal for Lake Huron water with no reconnection fee

Ron Fonger | rfonger1@mlive.com By **Ron Fonger | rfonger1@mlive.com**
on January 16, 2015 at 5:51 PM, updated January 17, 2015 at 9:50 AM

Sue F. McCormick

FLINT, MI -- The Detroit Water and Sewerage Department says it is "ready, willing and able" to start selling Lake Huron water to Flint again, and wouldn't charge a **$4 million reconnection fee** to get things started.

DWSW made the offer in a Jan. 12 letter to Flint's mayor and emergency manager, but it wasn't immediately clear whether the "long-term arrangement" offered by Detroit was also available for a relatively short-term period.

Flint and Genesee County are expected to have their own source of Lake Huron water once the Karegnondi Water Authority completes work on a new transmission pipeline by the end of 2016.

The city and county are partners in the KWA. The emergency manager's office issued a statement Friday, Jan. 16, saying the DWSD proposal would increase the cost of water by more than $12 million per year at the proposed rates, and could increase even more because rates are subject to change after July 1.

"This increase in costs would not be in the best interests of the city or its water users, as the city is committed to assuring safety and improving water quality by following its current plan, and reconnecting to DWSD would likely require deferment of existing capital improvements or an additional increase in rates," the statement says.

DWSD Director Sue F. McCormick's letter said Flint residents can go back to drinking lake immediately -- something some City Council members have advocated.

The letter says Detroit would sell treated lake water to Flint for a fixed monthly rate of $846,700 and $14.92 per 1,000 cubic feet as part of a "long-term arrangement" between the two cities.

Flint Mayor Dayne Walling declined to comment on the offer and has said he doesn't believe Detroit is part of the solution to Flint's water challenges

But 1st Ward Councilman Eric Mays said the offer opens the door to further talks.

Mays said he's talked to McCormick and wants the director to be part of a panel discussion about Flint's water supply next week.

"The people I'm talking to want good water yesterday," Mays said. "She said we can cut it (the water) on, cut it off" as needed.

Asked whether the DWSD offer would be available for just a few years, DWSD spokesman Greg Eno said in an email that McCormick's letter "speaks for itself."

"DWSD is wide open to sitting down with the Flint officials to further discuss how the department might be able to provide a solution to the city's water quality issue," Eno said.

Detroit's offer to re-establish a water supply to the city comes as Flint has struggled to harness the Flint River as a source of drinking water -- an effort that started in April.

Flint is in violation of the Safe Drinking Water Act because of the high level of trihalomethanes in water tested last year. Residents in scattered areas were hit by boil water advisories because of bacteria in 2014, the first time the city used the Flint River as its drinking water source in 50 years.

Resident have protested the price and quality of river water in various meetings since the switch. Several of the meetings have come since the trihalomethanes violation was reported to residents two weeks ago.

McCormick said she wrote to city officials here after reading about Flint's water problems on MLive-The Flint Journal.

Lockwood, Andrews & Newnam, an engineering contractor for Flint, raised the question of reverting to water from the Detroit in a Nov. 26 report to the city.

The report concludes that "utilizing the DWSD for interim supply is cost-prohibitive under the terms defined by DWSD," but McCormick said in her letter that the report appears to have been based on "some incorrect assumptions."

"I write to you today to express the willingness of DWSD to resume delivery of drinking water to the city and its residents," her letter says.

Flint mayor tells governor: Lower water connection fees, offer amnesty program for turn-ons

Ron Fonger | rfonger1@mlive.com By **Ron Fonger | rfonger1@mlive.com**
on January 20, 2015 at 6:15 PM, updated January 20, 2015 at 6:18 PM

Flint Mayor Dayne Walling shuts off a valve to close the supply of water from Detroit to Flint in this April 25, 2014, file photo.

FLINT, MI -- Mayor Dayne Walling says access to clean, safe, affordable water is a basic human right, and Gov. Rick Snyder has the responsibility for helping to deliver it.

Walling, in a post on his re-election campaign Web site on Monday, Jan. 19, called for Snyder to take actions ranging from lowering charges for new water customers in Flint to requiring more frequent reporting on water test results statewide.

"Both the state and federal government need to be actively involved in improving Flint's water system," Walling said Tuesday, Jan. 20. "The governor has a particular responsibility due to Public Act 436," the state's emergency manager law.

The mayor said his request has been sent to Snyder, and he asked his supporters to contact the governor as well if they want "to implement my plan and ensure Flint's water is safe."

Dave Murray, a spokesman for Snyder, said the mayor's request will be taken under consideration once it is received. Flint has been under state financial management since 2011 and Walling and the Flint City Council have had limited involvement in City Hall decision-making since.

Walling's plea to the governor comes as Flint officials are working to reassure customers about the quality of their water, which is the most expensive of any municipality in Genesee County.

The city is hosting a water presentation on Wednesday, Jan. 21, detailing water treatment, distribution and steps taken to ensure that "citizens get water that meets all regulatory safety and quality standards."

The presentation and Walling's request to the state come in the same month that the city told customers that Flint was in violation of the Safe Drinking Water Act because of the high level of trihalomethane (TTHM) in drinking water samples last year.

Earlier in 2014, several boil water advisories were also issued by the city because of issues with bacteria found in water in some parts of the city.

Walling has been among city officials who have tried to reassure customers that Flint water is safe. The city began using the Flint River as a temporary source of drinking water in April.

But the mayor said Tuesday that changes are needed in addition to calming words.

"It's non-negotiable that the city will have a safe and affordable water system going forward," he said. "Clearly, there are a number of unresolved issues with the current system."

"Everybody deserves an opportunity to pay their bill and get back in good standing" the maayor said. The city's water system "is better off from a health and financial perspective with more customers," he said.

The new plan is general in its outline, but is patterned in some ways after changes made to the Detroit water system, according to Walling.

Here are some of his requests to the state:

- Support alternatives for those advised not to drink the water by their doctors through the Michigan Health Endowment Fund and community partners to protect senior citizens and infants.
- Hire experienced river water treatment operating management in Flint.
- Require water testing data to be released quarterly by law in all Michigan communities.
- Announce an amnesty program aimed at making it easier for people to have water service reconnected and reduce the turn-on cost in Flint.
- Develop a revised payment plan policy to allow customers to come back to the Flint system, and establish a new statewide Drinking Water Emergency Assistance Fund.
- Accelerate water system improvements outlined in Flint's Capital Improvement Plan through federal and state investments.

Provide federal and state forgiveness of payments to the Drinking Water Revolving Loan Fund and federal and state financing for future improvements.

- Develop a community partnership to provide household and business customers with information on testing and conservation.

- Expand a youth energy initiative to assist households with conservation and efficiency. A pilot program was carried out in summer 2014 with Northwestern High School students, EcoWorks and Consumers Energy.

STATE OF MICHIGAN CONTRACT NO. 271N3200089

CITY OF FLINT WATER SUPPLY ASSESSMENT

At the request of the Treasurer, Tucker, Young, Jackson, Tull, Inc. (TYJT) makes the following recommendation to the Department of Treasury concerning Flint's water supply alternatives. Based on the financial analysis performed of the various options presented by DWSD to continue treated water service to Flint compared to Flint being supplied by the new KWA untreated water system, TYJT believes that several of the options presented by DWSD are lower in cost currently and over the long run than the one offered by KWA. TYJT also believes that DWSD's most recent offer (subsequent to the submittal of our report) to build a smaller parallel water main from Imlay to Flint, funded by the entire DWSD base of customers, is the best solution offering the least cost alternative and the required redundancy by MDEQ.

Furthermore, since a majority of the KWA system has not been designed and none of the system has been constructed, there is an additional risk that the cost of the KWA system may actually be higher than estimated due to potential construction delays and unforeseen conditions. This risk to Flint could be substantial since the city is responsible for 30 percent of the KWA design and construction costs while still having to purchase water from DWSD during the construction period.

Finally, there are other issues that were identified in our report that may result in risks to Flint if it were to join KWA that should be considered by the Treasury in determining how Flint's potable water should be supplied. These issues are related to redundancy and reliability, other items affecting cost, and Flint's desire to control its own destiny related to its water supply. These are described further below.

- DWSD's supply to Flint is via a 72-inch water main from Imlay City. This main also supplies Imlay City, Mayfield and the Greater Lapeer County Utilities Authority (GLCUA). The volume of water contained within the 72-inch main is approximately 30 million gallons. If Genesee and Flint move to KWA then the three remaining communities' consumption would most likely not be large enough to maintain fresh water in DWSD's pipeline (due to loss of chlorine residual). DWSD may consider shutting down the 72-inch line completely due to the water quality concerns, which would then create an additional burden for Imlay, Mayfield and GLCUA to finance treated water supplies.
- The KWA supply option is counter to the Treasury's Competitive Grant Assistance Program (Formerly EVIP Grant). This program has been put in place to allow for communities to consolidate their services and save money. Two existing customers of DWSD (Flint and Genesee County) along with the potential of others customers (GLCUA, Mayfield, Imlay City) separating from another water system is in contradiction to the program.
- There is a concern over the ability of smaller systems (KWA) over larger systems (DWSD) to pay for future unfunded mandates and regulations. Obviously, identifying regulation requirements over 30 years is hard to determine. However, it is widely accepted that a large system has greater ability to respond to unfunded mandates because the cost can be distributed over a large customer base.
- Although Flint will be responsible for 30 percent of the construction cost, they will only have a minority vote on the KWA board. Furthermore, there are other communities (Lapeer County, the City of Lapeer, and Sanilac County) that sit on the board and vote. However, they are not purchasing water nor contributing to the construction costs. Their position on the KWA Board will not provide them an ability to "control their own destiny," as they have stated to the Treasury.

1. INTRODUCTION

Tucker, Young, Jackson, Tull, Inc. (TYJT), at the request of the State Treasurer performed an analysis of the water supply options being considered by the City of Flint. The City of Flint is presently supplied potable water from the Detroit Water and Sewerage Department (DWSD). This supply is from a single 72-inch water main that terminates at a master meter located at Potter and Baxter. Additionally, downstream of the DWSD master meter, Flint supplies its customer Genesee County. The City of Flint also operates a water treatment plant that uses the Flint River as its source of supply to provide back up and redundancy to the DWSD supply as required by MDEQ

The Karegnondi Water Authority (KWA) is planning on constructing a raw water supply system that could provide Lake Huron water to the Flint Water Treatment Plant. Flint's existing plant would be upgraded to treat the new raw water source.

The State Treasurer has appointed an emergency financial manager for the City of Flint. As such the Treasurer has requested TYJT to provide an analysis of the water supply options to assist the Treasurer in determining any potential risk and the best course going forward for supplying potable water to the City of Flint.

Report Organization

The following sections of this report are described below:

Section 2 – The basis of the analysis is described in this section. The options include the KWA option and several options offered by DWSD.

Section 3 – A significant amount of information and data was collected including memorandums, reports, drawings, financial reports, and other documents. This section summarizes the information used in the analysis.

Section 4 – This section describes the evaluation of the cost of supply for the Flint options. The costs are comprised of the initial cost of operations plus the annual rate of escalation/inflation.

Section 5 – The evaluation process used to analyze the construction costs associated with the KWA supply system is described in this section. Additionally, the cost of financing the capital requirements is described.

Section 6 – This section presents the financial review of the options considered to supply potable water to Flint. A summary of these options is also provided.

Section 7 – In addition to the financial analysis other considerations were identified that should be considered in understanding the risks and determining the best option to supply Flint. They include items related to cost, redundancy and reliability, and Flint's ability to control their future cost of water supply.

2. FLINT WATER SUPPLY OPTIONS

Two water purveyor options were evaluated; the KWA water supply system and continued supply from DWSD. Both suppliers would provide water from Lake Huron as the source. The KWA system is a raw water supply, which means that the water would have to be treated by Flint before distributing the potable water to its customers. The DWSD supply is potable or "finished" water and would not need additional treatment.

Additionally, an option for the Flint WTP to supply the City of Flint without being supplied from either DWSD or KWA was initially considered. The preliminary investigation evaluated the cost associated with the required improvements to the plant and to the Flint River dam system. Although it appeared that this was a viable option, Flint in a meeting on December 20, 2012 with the Treasury, stated that the City did not want to pursue the option and it is no longer being considered.

Karegnondi Water Authority (KWA) Lake Huron Water Supply

The KWA water supply system schematic is shown in Figure 2-1. The system is comprised of an intake in Lake Huron that supplies water to the Lake Huron Pump Station (LHPS). The LHPS lifts the water and pumps it through an approximately 22 mile long 60-inch pipeline. The pipeline terminates at a 5 MG reservoir and is then pumped from the Intermediate Pump Station (IPS) through approximately 26 miles of 60-inch and 18 miles of 30-inch pipeline to the existing Flint WTP. Downstream of the IPS, approximately half way to the Flint WTP, the 60-inch line would also supply a new Genesee County WTP.

The raw water transmission system has a 60 MGD capacity and is sized to deliver a maximum of 18 MGD to the Flint WTP with an average day supply of 12 MGD. Improvements at the Flint WTP would also be required to treat the lake water as the plant is currently designed to treat the Flint River water.

The term of the KWA contract for Flint is 40 years.

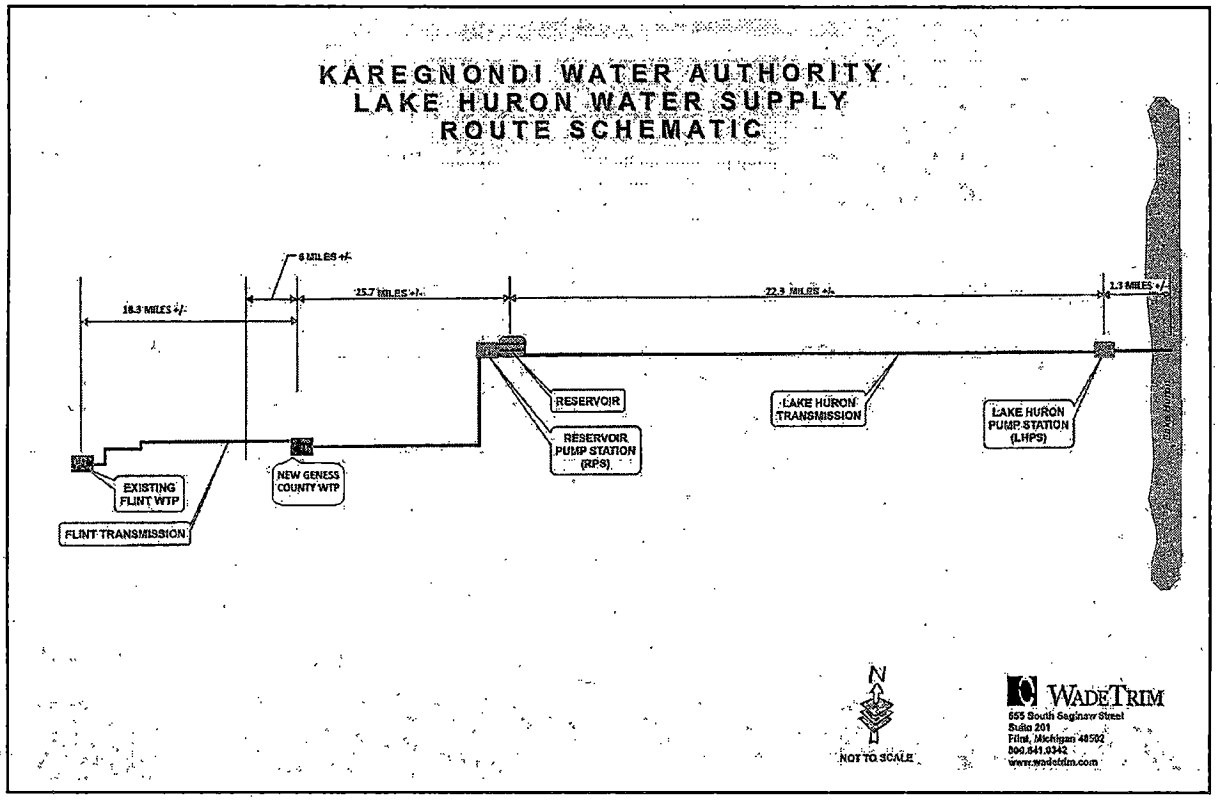

Figure 2-1: KWA Raw Water System

DWSD Water System

The DWSD system schematic is shown in Figure 2-2. Flint is currently supplied by DWSD at Master Meter FL-1, located at Potter and Baxter. Flint typically gets its water from the Lake Huron WTP, located in Fort Gratiot, Michigan; near the Lake Huron shoreline. Water is treated and pumped at the Lake Huron WTP and supplied through a 120-inch pipeline to an intermediate pump station called the Imlay Pump Station. The Imlay Pump Station has 20 MG of reservoir capacity. Depending on the time of year and the DWSD system demand, water is either bypassed directly to Flint or it is re-pumped at Imlay. It should be noted that the DWSD supply to Flint is part of a very large water system and during emergencies or outages water can be supplied from the south up to Flint in lieu of the Lake Huron facility.

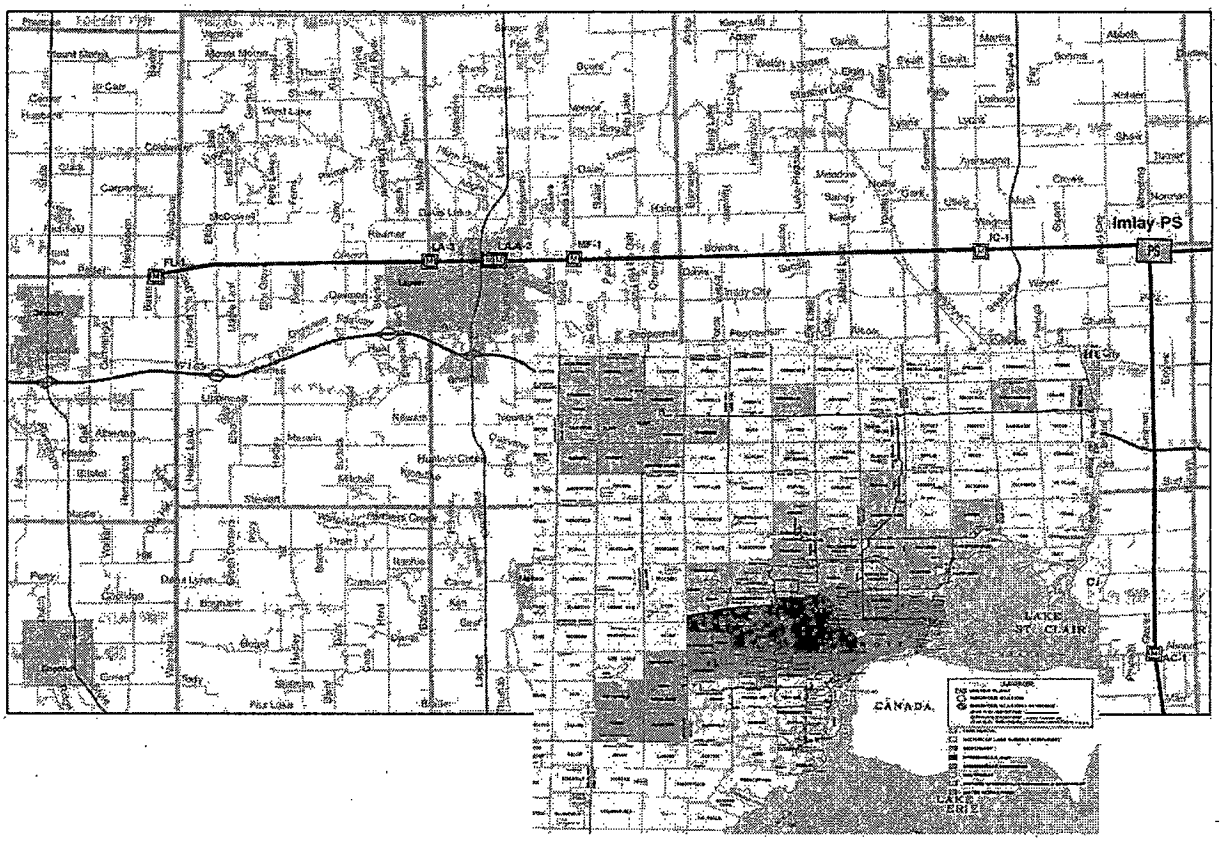

Figure 2-2: DWSD Water System

The pipeline from Imlay to FL-1 is a 72-inch pipeline. It has been estimated that the 72-inch line serving Flint has a capacity in excess of 90 MGD.

DWSD has presented several contractual options to Flint and all of them are based on Flint signing a new 30 year contract. The options shown in Table 2-1 are based on two different supply points; one at the current master meter location FL-1 at Potter and Baxter (P&B) and the other at the location of the Imlay Pump Station.. The reason for the varying options is to provide a lower water rate at the Imlay Station, since the DWSD rate formula is based on distance and elevation factors related to the supply location.

The rates are also dependent on the maximum amount of water DWSD supplies. As example, if DWSD supplies a maximum day demand of 18 MGD that would equal the entire amount of water required by Flint.

For the options less than the maximum of 18 MGD means that the Flint WTP would supplement the difference by supplying water treated from the Flint River. These options are known as "blending" and would allow for Flint to blend two sources of water to supply its customers; the Flint River using the Flint WTP and Lake Huron from DWSD system.

Description	Average Day Demand
18 MGD Maximum Day Customer – FL-1	12 MGD
12 MGD Maximum Day Customer – FL-1	8 MGD
8 MGD Maximum Day Customer – FL-1	8 MGD
12 MGD Maximum Day Customer - Imlay	12 MGD
8 MGD Maximum Day Customer - Imlay	12 MGD

Table 2-1: DWSD Supply Options

3. DATA COLLECTION

During the course of the investigation several documents were used to perform the analysis. The names of the documents are listed below for reference.

KWA and Flint

- Preliminary Engineering Report, Lake Huron Water Supply Karegnondi Water Authority, September 2009;
- Analysis of the Flint River as a Permanent Water Supply for the City of Flint, July 2011;
- Cost Comparison, KWA vs. DWSD, Letter to Mr. Kurtz, October 31, 2012;
- Lake Huron Supply Study, KWA, Appendix 20, October 2012 Preliminary Report Update, Final Report (DRAFT), October 4, 2012;
- Articles of Incorporation of Karegnondi Water Authority, endorsed in 2010;
- Karegnondi Water Authority Bylaws, October 26, 2010;
- KWA Raw Water Supply Contract;

- Historical Rates and Charges to Flint 04' – 13';
- Historical Rates and Charges to Flint with Hypothetical Model Contract 10' – 13';
- 2013 Rates and Charges for the following options:
  - 18 MGD Maximum Day Customer at FL-1;
  - 12 MGD Maximum Day Customer at FL-1 (Flint blending*);
  - 8 MGD Maximum Day Customer at FL-1 (Flint blending*);
  - 12 MGD Maximum Day Customer at Imlay (Flint blending*);
  - 8 MGD Maximum Day Customer at Imlay (Flint blending*); and
- Assorted emails with further clarification of questions and documentation.

* Flint blending based on DWSD supplying two-thirds and Flint one-third of 12 MGD average day demand.

Two meetings were also held; one with DWSD and one with Flint and Genesee County representing KWA. The meetings were held on November 19, 2012 and November 20, 2012, respectively. Minutes from these meetings are included in Appendix A.

4. COST OF SERVICE

Information provided by DWSD, Flint, and representatives of the KWA were used in the cost of service evaluation. To evaluate the annual escalation/inflation rate over the planning period, the rate adjustment for DWSD was estimated based on the recent rate adjustment history. For the KWA system both the estimated cost of operations when the system begins supplying water and the annual rate adjustment or inflation was evaluated. The existing cost of operations and escalation for the Flint WTP was based on actual costs provided and then adjusted depending on the scenario considered. This section describes the evaluation process and the rates used in the analysis.

DWSD Water Supply

The City of Flint has been a customer of DWSD since 1967. The Flint WTP has been maintained as a backup to the DWSD system. As indicated previously, several options were provided by DWSD depending on the type of service Flint was to select. The unit cost of water for each of these options is shown in Table 4-1. These rates are based on DWSD's FY13, which are current until July 2013.

Description	Average Day Demand (MGD)	Unit Rate ($/MCF)
18 MGD Maximum Day Customer – FL-1	12	16.37
12 MGD Maximum Day Customer – FL-1	8	16.31
8 MGD Maximum Day Customer – FL-1	8	12.68
12 MGD Maximum Day Customer - Imlay	12	14.38
8 MGD Maximum Day Customer - Imlay	12	11.11

Table 4-1: Cost of DWSD Supply Options

To determine annual escalation rate, DWSD's last 10 years of history was used along with other large urban water systems in Michigan. The water systems used for benchmarking comparison were: Lansing, Grand Rapids, and Saginaw.

Table 4-2 identifies the annual and average rate of increase to Flint based on supplying water either to the current FL-1 at Potter and Baxter or Imlay. Note the last three years of the rates (FY 2011 through FY 2013) assumes that Flint's cost would be based on the new 30 year contract; FY 2011 being the first year that the new contract was available.

Fiscal Year	Average Unit Cost ($/MCF)	Annual Change (%)
2004	11.06	
2005	10.24	-7.4
2006	10.56	3.1
2007	11.09	5.0
2008	11.35	2.3
2009	13.07	15.2
2010	11.73	-10.3
2011	13.89	18.4
2012	15.08	8.6
2013	16.24	7.7
Average		4.4%

From FL-1

Fiscal Year	Average Unit Cost ($/MCF)	Annual Change (%)
2004	11.06	
2005	10.24	-7.4
2006	10.56	3.1
2007	11.09	5.0
2008	11.35	2.3
2009	13.07	15.2
2010	11.16	-14.6
2011	12.23	9.6
2012	13.28	8.6
2013	14.32	7.8
Average		2.9%

From Imlay

Table 4-2: Recent DWSD Water Rates

Audited financial reports were used to determine the rate of inflation associated with other three large municipal systems. The results are shown in Table 4-3.

Water Systems	Years Evaluated	Average Rate (%)
Lansing	05'-12'	4.6
Grand Rapids	04'-11'	1.6
Saginaw	04'-11'	7.0

Table 4-3: O&M Inflation Rates of Other Large Water Systems

Based on the information analyzed from DWSD and the other communities, it was determined that a fair annual rate of inflation for operations and maintenance cost for the analysis should be 4.4%. The 4.4% has historical significance from Flint's current water supplier and falls within the range of the other communities.

KWA Water Supply

The initial projected O&M cost for the KWA supply would be comprised of KWA's O&M costs as well as Flint's O&M costs. Because there was limited information provided, the initial estimated rate of $1.50/MCF was used. This rate is based on information from the cost comparison analysis attached to the letter to Mr. Kurtz, dated October 31, 2012.

The KWA cost evaluation used an annual O&M inflation rate of 5%. To validate this rate a similar analysis to DWSD's operations and maintenance annual rate of inflation was used. First, in discussions with Flint and the Genesee County Drain Commission (GCDC), they believed that the annual rate of inflation for the new KWA system would be similar to the GCDC Water & Waste Services (WWS). Additionally, two large transmission systems were used to benchmark the inflation rates: the Southeastern Oakland County Water Authority (SOCWA) and the Ypsilanti Utility Community Authority (YUCA). Although both of these systems transmit finished water opposed to raw water, they were considered similar enough for comparison as they are comprised of only large water mains, pumping facilities and storage.

Once again audited financial statements were used to calculate the inflation rates. A summary of the findings are shown in Table 4-4. Based on the fact that the information analyzed showed a large difference between the two systems, it was determined that the KWA assumption of 5% was a good rate of inflation to use in the financial analysis. This rate is almost equally between the GCDC rate and the other two transmission systems.

Systems	Years Evaluated	Average Rate (%)
GCDC WWS	03' – 11'	10.5
SOCWA	04'-12'	--
YUCA	04'-12'	0.7

Table 4-4: O&M Inflation Rates of Other Comparable Systems to KWA

Flint WTP

The Flint WTP currently serves as a backup supply to the DWSD service to Flint. To maintain backup operations, the City of Flint operates the plant approximately 20 days each year. Flint indicated that the average production rate when they operate is 11 MGD.

For the blending options and the KWA supply considered, Flint would be required to operate its plant all year around. Therefore, their operating and maintenance costs were evaluated and adjusted to determine an annual cost associated with year-round operations.

The Flint WTP provided three years of operating costs for the assessment. Additionally, reports listed in Section 3 were also used as reference to determine both operating costs for the plant processing Flint River water (blending options) and Lake Huron raw water (KWA option).

Major cost centers were analyzed to estimate annual operation and maintenance. They included: labor, utilities, chemicals and residual management. In general, as recommended by the Flint plant staff, labor and overhead were increased from the current costs by two-thirds. Additionally, variable costs for power, chemicals and residual cost were increased to estimate full time treatment at the Flint WTP. Data from the KWA Preliminary Report and annual operating data for the Flint WTP (provided separately) were analyzed to make these forecasts.

The annual operating and maintenance costs developed for Flint WTP used are shown in Table 4-5.

Source of Supply	Average Daily Production (MGD)	Estimated Annual O&M Cost
Flint River (Blending with DWSD)	4	$5,895,097
Lake Huron (Supplied by KWA)	12	$7,913,118

Table 4-5: FY 13 O&M Costs for Year-round Operations

It was determined that a fair annual rate of inflation for operations and maintenance cost for the Flint WTP plant should be 4.51%. The 4.51% is an average of Lansing, Grand Rapids and Saginaw facilities.

5. CAPITAL REQUIREMENTS

Large capital investments would be required by Flint and GCDC to construct the KWA supply system. Furthermore, some of the options presented by DWSD (supply point from Imlay) would require the purchase by Flint of DWSD's 72-inch water main. Performing the financial analysis; therefore, required an analysis of the KWA construction cost estimate for the transmission system and Flint WTP improvements.

Revenue bonds were also identified as the source of financing the new supply system and associated improvements. This section describes the assumptions made and the interest used for financing the improvements.

KWA Supply System

The most current cost estimate of the KWA system was presented in the document titled; Lake Huron Supply Study, KWA, Appendix 20, October 2012 Preliminary Report Update, Final Report (DRAFT), October 4, 2012. The cost of construction is estimated at $272,421,558. Flint's portion would be 30% or $81,726,467.

Due to the significance of this expenditure, a detailed review of the cost was performed and is presented in this section. The analysis was performed based on the main elements of the supply system: the lake intake, the two pumping stations, and the transmission pipeline. Additionally, an analysis was performed related to construction contingencies and other costs such as engineering, legal, and administration.

Lake Intake

KWA representatives indicated in a meeting in November that the design documents for the intake were at 90% and that it was planned for advertisement in January 2013. A summary of the estimate is shown in Table 5-1.

Description	Estimate
Intake and Crib	$22,076,850
ELAC at 25%	5,519,213
Property	2,300,000
Total	**$29,896,063**

Table 5-1: KWA Intake Cost Estimate

Based on the evaluation, it appeared that the cost estimate was reasonable. Given that the design was nearly complete, the engineering, legal, administration, and construction contingencies (ELAC) at 25% were also found to be appropriate.

Pumping Stations

KWA representatives indicated that the pump stations were estimated at a level of design less than 15%. Therefore, in addition to an evaluation of their cost estimate, other water pumping station costs were used for comparison. Additionally, contractors were also contacted for costs. Table 5-2 summarizes the KWA cost estimate compared to our cost estimate performed for the Treasury.

Description	KWA	Estimate	TYJT	Estimate
Pumping Stations		$24,618,080		$54,573,314
Land for Intermediate Pump Station and Reservoir		--		75,000
Subtotal		$24,618,080		$54,648,314
ELAC for Construction	25%	6,154,520	30%	16,394,494
Total		**$30,772,600**		**$71,042,808**

Table 5-2: Pumping Stations Cost Estimate

Two things to note regarding the difference in the cost estimates; firstly, there is a large difference in the cost estimates of the pumping stations. The estimate developed for the Treasury used several other pumping stations construction costs from Southeastern Michigan and discussions with contractors. These costs were then computed on a $/MG's for comparison.

Secondly, our estimate for the Treasury is based on an ELAC of 30% instead of KWA's 25%. Although 25% was acceptable for the intake, it is believed to be too low for the pumping station estimate given that the engineering effort is less than 15%.

Transmission Main

Although the specific route for the transmission main was not provided, an estimate was calculated based on the general information provided. Once again, the KWA estimate was based on a level of design less than 15%. The estimate performed for the Treasury used the line items provided by KWA for the pipeline and also consulted with contractors to evaluate the cost of construction. The comparison is shown in Table 5-3.

Although the cost of construction of the pipeline is similar, a value of 30% was used for ELAC due to the level of design. Additionally, KWA did not believe there would be any additional costs for easements; however, this did not seem practical. Therefore an estimate for acquiring the easements was added to the Treasury estimate and is based on the 277 easements identified by KWA. The cost shown includes surveying, legal, engineering, administration, etc.

Description	KWA	Estimate	TYJT	Estimate
Transmission Mains		$166,202,316		$167,419,530
ELAC for Construction	25%	41,550,579	30%	50,225,859
Subtotal		$207,752,895		$217,645,389
Easements		--		1,166,170
Total		**$207,752,895**		**$218,811,559**

Table 5-3: Transmission Pipeline Cost Estimate

Other KWA Costs

In prior estimates of the construction cost, KWA used an ELAC of 37%. In this case it could be considered that the engineering effort associated with the design would have been included. However, it is believed that KWA's reduced ELAC of 25%, does not include the design effort. Additionally, it would be prudent to assume that the owner would want a construction manager during construction of this large project. A summary of these costs are shown in Table 5-4.

Description	Estimate
Design Engineering for Pumping Stations and the Transmission Pipeline	$16,939,581
Construction Management at 5%of Project Cost Estimate of $217,645,389	14,434,609
Administration	349,440
Legal, Easements, Contract Documents	831,000
Total	**$32,554,630**

Table 5-4: Other Costs

Summary Comparison

A summary of the two cost estimates are shown in Table 5-5. Based on the comparison, the estimate performed by TYJT shows a higher cost to Flint by approximately $25,000,000.

Note that there are two other costs shown in the summary that were not previously addressed; power and backup power. Regarding the cost of providing power to the pumping facilities, the cost of $4,000,000 appears reasonable.

The KWA has repeatedly indicated that backup power is not needed. Backup power is a standard practice in the water industry. Furthermore, a loss of power at either pumping facility will prevent the supply of water to both Flint and Genesee County. For these reasons, the cost of providing backup power was included in our estimate for the Treasury.

Description	KWA Estimate	TY/T Estimate
Intake/Crib	$ 27,596,063	$ 27,596,063
Pump Stations	30,772,600	71,042,808
Transmission Mains	207,752,895	217,645,389
Power	4,000,000	4,000,000
Redundant Power for PS		1,273,200
Land for Lake Huron Pumping Station	2,300,000	2,300,000
Design Engineering/PS and Transmission		16,939,581
Construction Management		14,434,410
Administration		349,440
Legal/Easement/Contract Documents		831,000
Easements		1,166,170
Total	**$ 272,421,558**	**$ 357,578,060**
Flint Share at 30%	**$81,726,467**	**$107,273,418**

Table 5-5: Total Cost Comparison

Flint WTP Improvements

The KWA analysis identified capital costs required to convert the existing WTP from river water treatment to treating lake water. The cost estimate was identified as $7,100,000 in the 2009 report. This number was used in the our analysis, since additional information was not provided. For the purpose of the financial analysis; however, the $7,100,000 was increased by 3% each year for three years to account for inflation.

DWSD Imlay Station Supply Options

The options identified by DWSD to supply service to Flint at the Imlay Pump Station would require Flint to purchase the 72-inch water main from Imlay to Master Meter, FL-1. The pipeline is approximately 25 miles long. The estimated cost provided by DWSD for estimating purposes is $4,700,000.

Financing

The cost of financing the revenue bonds for the capital work was investigated. Based on conversations with local financial advisors knowledgeable in bond financing, an interest rate of 5% for the 25 year

period was considered acceptable. This is based on a Standard and Poor's bond rating of A without insurance.

Additional costs associated with the bond include the reserve and bond issuance fee. The bond holders will require a reserve of approximately 10% of the loan to be held for the 25 year payment period. The cost associated with the bond issuance has been estimated at 2.25% of the principal borrowed for the KWA project and 3% for the smaller loan associated with the Flint WTP improvements or the purchase of the 72-inch main.

Furthermore, since no revenue will be generated to pay on the bonds for the first three years that the system is being constructed, the cost associated with capitalizing the interest was also included.

Finally, interest on the reserve will be provided back to KWA and Flint. Although the interest is currently less than 1%, it was determined that a 3% rate would be more prudent long-term.

6. FINDINGS

Using the information described in the previous sections, a cost evaluation was conducted for the KWA supply and the DWSD options. Individual worksheets for each option are provided in Appendix B. For the purpose of comparison a 30 year period was used. This period includes the 3 year construction period, the 25 loan period and an additional two years to get a sense of the cost of operation after the loans have been paid.

There were three separate cost sheets prepared for the KWA option. The first cost sheet (KWA) is based on the cost estimate provided by KWA. The costs provided assumed no overruns or delay in construction. With KWA's own assumptions of an overrun in construction of 15% and a one year delay in operations, the KWA estimated cost becomes $686,375,920 through Year 2042.

Since this cost estimate did not appear to include the financing of revenue bonds, another cost sheet (KWA-1) was developed that included KWA's cost estimate without overruns with the additional finance costs associated with the revenue bonds. A final cost sheet (KWA-2) includes the cost associated with the revenue bonds based on the estimate provided by TYJT for the Treasury.

A summary of the cost sheets provided in Appendix B are shown in Table 6-1. Figure 6-1 shows the cumulative annual costs associated with each option.

Option	Costs through 2042 ($)	Ranking by Cost
DWSD 8 MGD Maximum Day at Imlay Station	634,795,488	1
KWA *(10/31/12 No Overruns, As Provided)**	649,775,166	2
DWSD 8 MGD Maximum Day at FL-1	672,671,705	3
KWA-1 *(10/31/12 No Overruns with Cost of Financing)*	707,279,715	4
DWSD 12 MGD Maximum Day at Imlay Station	725,576,803	5
DWSD 12 MGD Maximum Day at FL-1	762,110,308	6
KWA-2 *(Treasury Estimate)*	766,784,313	7
DWSD 18 MGD Maximum Day at FL-1	821,226,268	8

* $686,375,920 with 15% overrun in construction and a one year delay in operations

Table 6-1: Total Cost of Options through 2042

Based on the analysis, it is prudent to assume the KWA water supply option costs would be somewhere between the KWA-1 and KWA-2 options. Therefore, the analysis indicates that the two DWSD options of supplying 8 MGD on a maximum day and up to 8 MGD on average are the least cost options for Flint. These options allow Flint to maximize the use of existing assets; the City of Flint's (the Flint WTP) and DWSD's (the existing 72-inch main).

Additionally, in recent conversations with the Treasury another option was discussed that could potentially be the most cost-effective solution. Currently the Flint WTP serves as a backup if service is

lost through either the DWSD or KWA pipeline. If the a twin pipe paralleling the DWSD 72-inch water main were constructed with interconnects with the 72-inch line, then the new water main could serve as the backup to Flint and the Flint WTP could be abandoned or potentially sold to Genesee County for their use.

The construction of the parallel pipeline would be considered in the DWSD capital expenditure as a Common to All (CTA) cost. This means that the capital cost of the pipeline would be shared by all DWSD customers and not just by Flint. Preliminary analysis of this option appears to be the most cost-effective of all the options discussed. However, a more thorough cost analysis is warranted and this approach would require an agreement between Flint and DWSD.

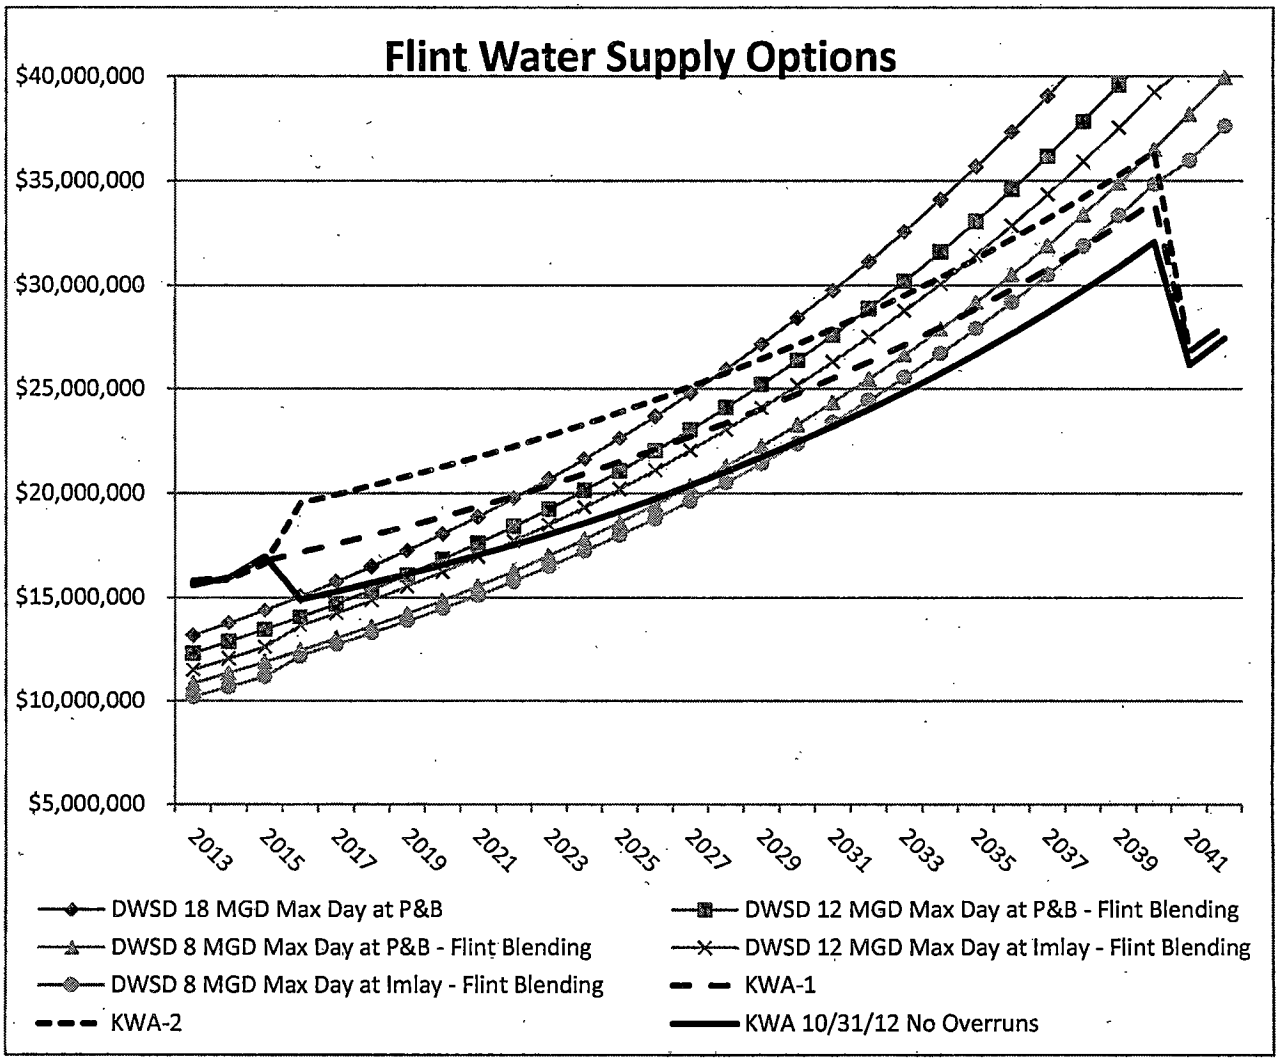

Figure 6-1: Flint Water Supply Options through 2042

Judge orders Flint to cut water rates 35 percent in sweeping injunction

Genesee Circuit Judge Archie Hayman issues Flint water ruling

Genesee Circuit Court Judge Archie Hayman makes ruling in Flint water case.

(This story has been updated with additional information.)

Attorney Val Washington speaks and holds up a folder containing documentation of all Flint residences that have had liens placed against their properties due to delinquent water and sewer bills after increased fees went into effect in 2011.

Flint Journal file photo

FLINT, MI -- Less than four months after the city's financial emergency ended, a judge's order has city officials talking about a potential bankruptcy all over again.

The city of Flint has been ordered to roll back water and sewer rates by **35 percent**, to end a ready-to-service fee, to repay its water and sewer fund by more than $15 million, and to stop water disconnections and liens for past-due bills effective immediately.

Genesee Circuit Judge Archie Hayman issued an emergency injunction today, Aug. 7, a decision city officials said has the potential to bankrupt Flint, which just emerged from a financial emergency in April.

Hayman said the city wrongfully transferred $15.7 million in water and sewer funds in 2007 to help settle a lawsuit involving sewage overflows -- money that must be returned, but told attorneys for two Flint water customers and the city to negotiate the terms of that payback.

"I am mindful that this could be devastating to the city so the court is not going to at this point make a ruling that the $15.7 million has to be paid immediately ... but that money has to be replaced at some point," Hayman said.

The city issued a statement from City Attorney Peter Bade today, saying the ruling "is striking in terms of both its deviation from Michigan law, as well as the immediate financial harm it will cause the City of Flint.

"This will have a devastating financial impact," Bade's statement says. "The City will immediately seek a stay of this order and review by the Court of Appeals."

City spokesman Jason Lorenz said the city would have no further comment on the case today, but Mayor Dayne Walling released a statement, saying, "Flint needs a sustainable water system with affordable rates

and that is my objective. There are numerous problems with the judge's ruling that will be addressed through further court action."

Anthony Chubb, deputy chief legal officer for the city, asked Hayman for a stay in enforcing his ruling as the city appeals it to the state Court of Appeals, but the judge denied that request.

Chubb argued in court today that the requested injunction amounted to "a good political show" and said the ruling -- if it stands -- "would likely result in bankruptcy" for the city.

In issuing the injunction -- part of a lawsuit filed by two Flint water customers -- Hayman also:

- Told the city to eliminate a 35 percent increase in water and sewer rates enacted by Mayor Dayne Walling in 2011 because the hikes violated a city ordinance that required advance notice to customers and that requires such rate increases to be added over 12 months rather than immediately.

  Hayman said the state Court of Appeals also concluded former emergency manager Mike Brown did not have the authority to ratify Walling's water and sewer rate increases when that court issued an opinion in a related **lawsuit brought by City Councilman Scott Kincaid**.

  In June, the Court of Appeals reversed a decision by Genesee County Circuit Judge Richard Yuille, who dismissed the Kincaid lawsuit in 2013.

  That case is still pending in Circuit Court.

- Enjoined the city from collecting readiness-to-service fees until it complies with a city ordinance, requiring officials to justify those charges in writing.

  Hayman said the fees -- which amount to a $57.38 fixed charge for a typical residential customer -- can be collected but not without the city taking that step.

  City officials have said those fixed charges support maintenance of the water and sewer systems.

- Enjoined the city from enforcement of water liens and water disconnections because of past-due bills.

  Attorney attorney Val Washington said liens have been filed against more than 13,000 homes and businesses in Flint based on "illegal water rates."

- Ordered attorneys for the city to negotiate with Washington on how to pay back $15.7 million that was "wrongfully taken" from water and sewer funds.

"There's no ordinance that allows for that," Hayman said. "State law does not allow for that. The mayor at the time did not have the authority to go in and invade the water supply account."

Flint's mayor at the time of the transfer was Don Williamson.

Hayman told attorneys to work toward a plan for payback of the $15.7 million to the water and sewer fund by the end of October -- before returning to court Nov. 13.

Washington said the city has been unwilling to negotiate a settlement of the lawsuit, which was filed by Flint residents Larry Shears and Margaret Fralick in 2014.

CITY OF FLINT

Dayne Walling
Mayor

January 18, 2015

The Honorable Rick Snyder
Governor, State of Michigan
P.O. Box 30013
Lansing, MI 48909

RE: Flint Water Improvement Plan

Dear Governor Snyder:

On behalf of the Flint community, I am writing to convey serious concerns about water quality and to request your support for my proposed Flint Water Improvement Plan. Access to safe and clean water is a basic human right, and, therefore, policy and budget decisions need to ensure that water is affordable and secure for everyone in Flint and all across Michigan. It is essential there is City, State and Federal cooperation to address the challenges here and to meet the needs of vulnerable populations.

The Flint Water Improvement Plan is focused in five areas: safety, quality, access, investment and education. The plan puts safety and quality first because this is fundamental. It is designed to be a sustainable solution for the City of Flint and the community as we move towards a new permanent water supply from Lake Huron through the Karegnondi Water Authority. My plan offers new ideas and also builds on successful models of utility, energy and assistance programs at the State and Federal levels.

Safety & Quality

- 100% Safety is the standard
- City of Flint reports testing data to the public to assure safety and expands testing sites and frequency
- Bring on experienced river water treatment operational management in the City of Flint

Access

- Announce an amnesty program for Flint water service turn-ons and reduce the turn-on fee
- Develop a revised affordable payment plan policy to encourage customers to return
- Design Federal and State partnership to establish new Drinking Water Emergency Assistance Fund for the elderly and vulnerable families

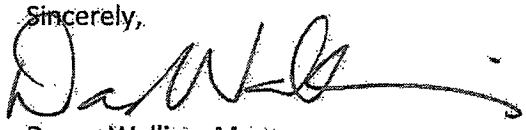
Investment

- Accelerate water system improvements outlined in the City of Flint Capital Improvement Plan through Federal and State investments
    - State approves City of Flint's Distressed Cities Fund applications

- Federal and State support for replacement or forgiveness of payment to the Drinking Water Revolving Loan Fund due to Flint's status as a distressed community
- Federal and State grants for infrastructure improvements in alignment with the Flint Master Plan

- City Water Department implements budgeted FY15 projects including leak detection, valve repairs, new pipes and meter replacements

Education



- Develop a community partnership with universities to provide household and business customers with information on testing and conservation
- Ongoing partnership with Michigan Department of Human Services, United Way, Salvation Army and community organizations to provide information and water assistance with the Keep the Water Flowing Fund and support services
- Expand youth energy initiative to assist households with conservation and efficiency (piloted in summer 2014 with Northwestern High School students, EcoWorks and Consumers Energy)

It is also critical to restore the public confidence in Flint Water. The implementation of this plan must be accompanied by extensive community engagement including local elected officials. My objective is to work with you and your appointed officials, State Senator Ananich, State Representatives Phelps and Neeley, Congressman Kildee, community groups, businesses, churches, foundations, the Flint City Council, and all of the City of Flint and government personnel.

It is imperative that we communicate better and provide residents more information. I understand representatives from the Michigan Department of Environmental Quality will be joining a public forum this week at City Hall. This engagement going forward is vital so thank you for supporting their efforts. I think this issue of transparency is important for communities all across the State. I recommend a review of the applicable laws and policies and, at a minimum, a new requirement that water testing data be reported publicly no less than quarterly by law in all Michigan communities in Flint's population category.

Thank you for the consideration Governor. There is nothing more important in Flint right now than fixing the water problems. We must work together to identify funds to repair and update the water treatment facilities and city-wide infrastructure and to help those persons without access to clean water so that the entire Flint community has sustainable, safe, secure and affordable water now and into the future. This is an important issue for the state of our State of Michigan and I urge you to work with us to implement solutions.

Sincerely,

Dayne Walling, Mayor
City of Flint

CC: Flint City Council President Joshua Freeman; Congressman Dan Kildee; State Senator Jim Ananich; State Representative Sheldon Neeley; State Representative Phil Phelps; Flint Emergency Manager Jerry Ambrose

Karegnondi Water Authority®

June 10, 2013

The Honorable Rick Snyder
Governor
State of Michigan
P.O. Box 30013
Lansing, MI 48909

Dear The Honorable Rick Snyder:

As the Karegnondi Pipeline project moves forward, I am excited to announce that we will be having an official groundbreaking for the project on June 28th. This represents a historic milestone, not only for the region, but for the entire state.

We will be holding the ceremony at the site where the intake will be built, near Port Huron. Details of the event are attached. While most people will drive themselves to enjoy the scenic view, we will be providing a bus to and from Genesee County with a LIMITED number of seats available. If you would like a spot on the bus you MUST **pre-register with my office prior to June 17th.** Seats will be first come first serve. Please call 810-701-6514 to pre-register. Please also note that this is a construction site, so casual dress should be used.

I realize this project has been decades in the making, and there are many individuals who have sacrificed much of their time to ensure that this day arrived. I truly hope that you are able to attend so that we may thank you and others for all of their hard work in seeing that the pipeline reached fruition.

The KWA is a game changer for our residents, and Michigan's economy overall. These days unfortunately come along much too infrequently. I hope to see you there so that we may celebrate our success together.

Regards,

JEFF

Jeff Wright
CEO – Karegnondi Water Authority

YOUR DOING A GOOD JOB GOVEROR! HOPE YOU COULD MAKE IT, AND SAY A FEW WORDS TO KICK THIS OFF.

Karegnondi Water Pipeline

Ground Breaking Ceremony

Please join us as we begin construction of the Karegnondi Waterline, taking the next step in water independence for our region!

Jeff Wright—Genesee County Drain Commissioner, cordially invites you to this historic groundbreaking ceremony.

After the conclusion of the program—Snacks and refreshments will be served.

Due to the distance of the construction site and limited parking , a bus will be provided leaving the Genesee County area at 8:00 a.m. **Deadline to RSVP for bus is June 17th.
(Seats will be first come first serve through pre-registration. You will receive further details at that point.) - **Bus is scheduled to return at 3:00 p.m.**

June 28th

10:00 a.m.

3900 Fisher Rd.
Lexington, MI

(see attached map)

- Please RSVP for **BOTH** attendance and transportation prior to **June 17th.**

Please RSVP to Kevin Sylvester at
810-701-6514

Program Agenda

10:00 a.m.—Introduction/Welcome .....Jeff Wright
Genesee County Drain Commissioner

10:05 a.m.—Invocation – .....Pastor Floyd Fuller
Mount Tabor Missionary Baptist Church

10:10 a.m.—Overview of Project .....Jeff Wright

10:30 a.m.—Key Stakeholders

Rick Hammel—Former Democratic House Leader

Jamie Curtis—Chair, Genesee County Board of Commissioners

Dayne Walling—Mayor, City of Flint

Nancy Nyquist—Department of Agriculture

Steven Busch—Department of Environmental Quality

Liane Shekter Smith—Department of Environmental Quality

Charles Smiley—State Representative

Pam Faris—State Representative

Kevin Daly—State Representative

David McGhee—Congressman Dan Kildee

Bryanna McGarry—State Senator Jim Ananich

Kevin Gardner—State Senator Phil Pavlov

Janice Karcher—Genesee Regional Chamber of Commerce

Greg Alexander—Sanilac County Drain Commissioner

11:15 a.m.—Official Groundbreaking of Karegnondi Pipeline

11:30 a.m.—Lunch will be served

1:00 p.m.—Ceremony Concludes—Have a safe trip home!!

Flint Water Timeline (11-09-15)

1. **June 26, 2012** – Letter from Flint EM Mike Brown to DWSD for permission to begin blending Flint River water with treated water from DWSD. The letter indicates that the DEQ is supporting this option and its implementation would save the City between $2M and $3M annually.

2. **September 20, 2012** – Letter from Flint EM Ed Kurtz to DWSD requesting written permission to implement the blending option. Approval is requested by October 1, 2012.

3. **October 31, 2012** – Analysis by the Flint Finance Director suggests that the annual cost to purchase water from DWSD will steadily increase to $23M per year by fiscal year 2020.

4. **November 2012** – Treasury retains Tucker, Young, Jackson and Tull (TYJT) to evaluate the KWA proposal to the City of Flint.

5. **November 6, 2012** – Letter from Flint Emergency Manager Ed Kurtz to State Treasurer Dillon that a proposal from DWSD is expected but that the initial assessment is that switching to KWA is in the best interest of the City of Flint.

6. **February 6, 2013** – TYJT issues a final report to Treasury on the comparison between Karegnondi Water Authority (KWA) and DWSD. Analysis suggests that the KWA option is the cheaper option for the City of Flint.

7. **March 2013** – DWSD contacts the City of Flint to begin direct negotiations on a contract extension. Multiple options are provided to the Flint Emergency Manager (EM) Ed Kurtz.

8. **March 25, 2013** – The Flint City Council endorses joining KWA.

9. **April 11, 2013** – State Treasurer Andy Dillon authorizes Flint EM Ed Kurtz, pursuant to Section 12(3) of P.A. 436 of 2012, to enter into a contract with KWA if a final offer from DWSD is either not received for rejected in good faith based upon specific objections.

10. **April 15, 2013** – DWSD provides a best and final offer to the City of Flint. Analyses by Flint EM Ed Kurtz, the Department of Environmental Quality and Treasury's Office of Fiscal Responsibility independently conclude that the KWA option is cheaper for the City of Flint.

November 24, 2015

Michigan Department of Environmental Quality
City of Flint Drinking Water Event Timeline
Q&A

I. INTRODUCTION

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), with respect to events in the city of Flint (City), Michigan.

II. BACKGROUND

1. How has Flint historically obtained its drinking water?

The water system in the City was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City. In 1967, the City became a customer of the Detroit Water and Sewerage Department (DWSD) system.

After the switch to DWSD, the City operated its water treatment plant as a standby plant for purposes of reliability in the event of an emergency, such as an interruption in service of the single pipeline from DWSD. In the last ten years, the water treatment plant was used as an emergency backup during two weeks in 2009: June 18 through June 20 and September 10 through September 13.

As a backup emergency water treatment plant, the City was required to operate the water treatment plant quarterly to demonstrate the capability to produce drinking water in accordance with Act 399 and to keep mechanical equipment (such as valves, rubber seals, etc.) in good working order. Each quarter, the water treatment plant was test run and samples were taken of both raw water and finished water (post-filters). Since the water treatment plant was upgraded in the early 2000s, monitoring showed that the water treatment plant was performing as designed.

Contractual obligations with DWSD did not allow treated water to be put into the City's distribution system during these test runs. Treated water was discharged to the Flint River in accordance with a National Pollutant Discharge Elimination System (NPDES) Permit. The test runs were for demonstration purposes, to keep the water treatment plant operational, and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules exist to ensure safe drinking water is provided to City residents?

The federal Safe Drinking Water Act (federal SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the federal SDWA, the United States Environmental Protection Agency (USEPA) sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.
The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended

The DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: conducting surveillance visits (inspections) at water systems and reviewing facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the training, examination, certification and regulation of persons operating water supplies; helping systems incorporate preventive measures; and since 1996, providing financial assistance for system improvements.

5. What is the City's role in implementing the federal SDWA and Act 399?

State and federal programs develop regulations and perform oversight and compliance activities, but do not treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers in compliance with state and federal regulations.

The federal SDWA and Act 399 set up multiple barriers against contamination. These barriers include: source water protection, multiple treatment components, distribution system integrity, proper operations oversight, and public information. As the owner of a public water system, the City is responsible for knowing and following all requirements under Act 399, such as ensuring proper design, construction, operations and maintenance, so that contaminants in tap water do not exceed the standards established by law. The City treats the water, and must test its water routinely for specified contaminants and report the results to the DEQ. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The federal SDWA and Act 399 recognize that customers have the right to know what is in their drinking water and where it comes from. The City, like all water suppliers, must notify consumers when there is a problem with water quality.

The City submits samples of its water for laboratory testing (monitoring) to verify the water it provides to residents meets all federal and state standards. How often and where samples are taken varies from system to system and from contaminant to contaminant. The DEQ provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the City is required to employ properly certified water operators that are trained and experienced to operate the treatment and distribution systems associated with the City's water system.

6. What approvals were needed from the DEQ in order for the City to begin using its water treatment plant full time?

The City had long ago been issued construction permits for raw water pumps to withdraw water from the Flint River and the City was grandfathered under the water withdrawal program (Part 327, Great Lakes Preservation, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended), as were all existing community public water systems at that time. There were no additional DEQ permissions or authorizations required under Act 399 because the City already had approval to use the water treatment plant.

April 2014 (DWSD) average pH = 7.49 range: 7.42 – 7.59

Note that the pH of the treated water produced while the City was using the Flint River did not differ significantly from pH values seen in the distribution system during the time the City purchased water from DWSD. Thus, pH monitoring provided no indication of a change in water corrosivity.

IV. *E. COLI* AND TOTAL COLIFORM BACTERIA VIOLATIONS

1. What caused the *E. coli* and total coliform bacteria violations experienced by the City in August and September 2014?

A number of factors, primarily related to distribution system operation and maintenance, likely contributed to the Boil Water Advisories in the City during August and September 2014 triggered by exceedances of bacteria standards in limited areas of the distribution system. In addition, the coliform detections were confined to less than 20 percent of the water system. Had the detections been the result of a failure in treatment, detections would have been expected throughout the City rather than in such a limited geographic area.

Instead, the violations seem to have been caused by other factors such as aging infrastructure. The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of unlined cast iron piping. This cast iron pipe is subject to tuberculation, which thins and weakens the pipe walls in some areas and causes a buildup of sediment and debris on the pipe walls in other areas. Tuberculation can lead to water quality issues as well as reduced flows and pressures. Tuberculation also encourages the development of biofilms. Biofilm growth may occur more frequently in areas where little or no disinfectant is maintained.

The City has also experienced decades of a declining customer base and water use, with vacant homes, commercial businesses, and industrial property. Declining water use leads to excess residence time (water age) within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and reductions of disinfectant concentration in the distribution system. While the City has recently seen an infusion of funding for blight removal, contractors using fire hydrants to complete this work have been known to cause hydraulic disturbances that dislodge and suspend settled debris, which may contribute to the bacterial contamination. These hydraulic disturbances were also believed to be a source of the aesthetic water quality complaints both the City and the DEQ were receiving.

The winter of 2013-2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30 percent, saw even greater losses since February 2014 due to an increase in cold weather-related water main breaks and leaks (City personnel reported 400 water main breaks in calendar year 2014, with greater than 50 percent in the winter quarter). The City has also been lacking a formal maintenance program for its more than 7,250 valves, which are critical in limiting the areas impacted during water main repairs. As an example, two valves on the transmission line used to supply the area of the 2014 Boil Water Advisories were found to be closed during the City's

collected and analyzed to confirm that bacteria are no longer present. Under approved analytical methods used by the City, samples must be incubated for 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a Boil Water Advisory. Adding each of these steps together, a normal response period to rescind a Boil Water Advisory under these circumstances would be expected to take 3 to 4 days.

V. TOTAL TRIHALOMETHANES (TTHM) VIOLATIONS

1. What caused the TTHM violations experienced by the City beginning in late summer 2014?

Disinfectants are an essential element of drinking water treatment because of the barrier they provide against waterborne disease-causing microorganisms. However, disinfection byproducts form when disinfectants used to treat drinking water react with naturally occurring organic materials in the water (e.g., decomposing plant material). The formation of disinfection byproducts continues to occur as water travels throughout water distribution systems.

A major challenge for water suppliers is how to provide protection from pathogens while simultaneously minimizing health risks to the population from disinfection byproducts. Total Trihalomethanes (TTHM – chloroform, bromoform, bromodichloromethane, and dibromochloromethane) and halogenated acetic acids (HAA5 – monochloro-, dichloro-, trichloro-, monobromo-, dibromo-) are widely occurring classes of disinfection byproducts. The amount of TTHM and HAA5 in drinking water can change depending on the season, water temperature, amount of chlorine added, the amount of plant material in the water, and a variety of other factors. All community water systems that chemically disinfect or purchase water that has been chemically disinfected are required to monitor for disinfection byproducts.

The Flint River has higher levels of organic material than water in the Great Lakes and as a result, the water produced by the City developed higher disinfection byproducts than the water purchased from DWSD. Because the water treatment plant was previously operating intermittently, it was not possible to predict disinfection byproduct levels at distribution system compliance points until the City began relying on its water treatment plant continuously.

As mentioned previously, the City became aware that there were numerous broken valves and closed valves that should have been open in the distribution system. At that time, the City also began a mapping effort to identify "water age" in the distribution system. The longer the residence time or "water age" the greater the opportunity for the formation of disinfection byproducts.

2. How were the violations detected? What was the DEQ's response?

Disinfection byproducts are monitored at eight sites throughout the distribution system. A locational running annual average is calculated for each individual site. Because TTHM and HAA5 maximum contaminant levels are calculated based on a running annual average at specific distribution system locations, the actual violation

VII. LEAD ISSUES IN THE FLINT DRINKING WATER

1. What causes lead in drinking water?

Lead is rarely found in source water. Lead enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead fixtures and solder. Older homes built prior to World War II are more likely to contain lead pipes. The most common problem with newer construction is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What is the Lead and Copper Rule?

On June 7, 1991, the USEPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR). The treatment technique for the rule requires systems to monitor drinking water at customer taps. If the 90th percentile for lead exceeds an action level of 15 parts per billion (ppb) or the 90th percentile for copper exceeds an action level of 1.3 parts per million (ppm), the system must undertake a number of additional actions to control corrosion. If the action level for lead is exceeded, the water supply must also inform the public about steps they should take to protect their health and the water supply may have to replace lead service lines under their control.

3. What is the lead action level?

For most contaminants, the USEPA sets an enforceable regulation called a maximum contaminant level based on the maximum contaminant level goal. Maximum contaminant levels are set as close to the maximum contaminant level goals as possible, considering cost, benefits, and the ability of public water systems to detect and remove contaminants at the water treatment plant using suitable treatment technologies. Because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, the USEPA established a treatment technique rather than a maximum contaminant level for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to control a contaminant. Although the maximum contaminant level goal for lead is zero, based upon the above factors, the USEPA has established the action level for lead at 15 ppb.

The treatment technique regulation for lead requires water systems that produce drinking water to control the corrosivity of the water. The regulation also requires systems to collect customer tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If the 90th percentile action level for lead is exceeded, then water systems are required to take additional actions including:

- Optimizing corrosion control treatment (for water systems serving greater than 50,000 people that have not fully optimized corrosion control).

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

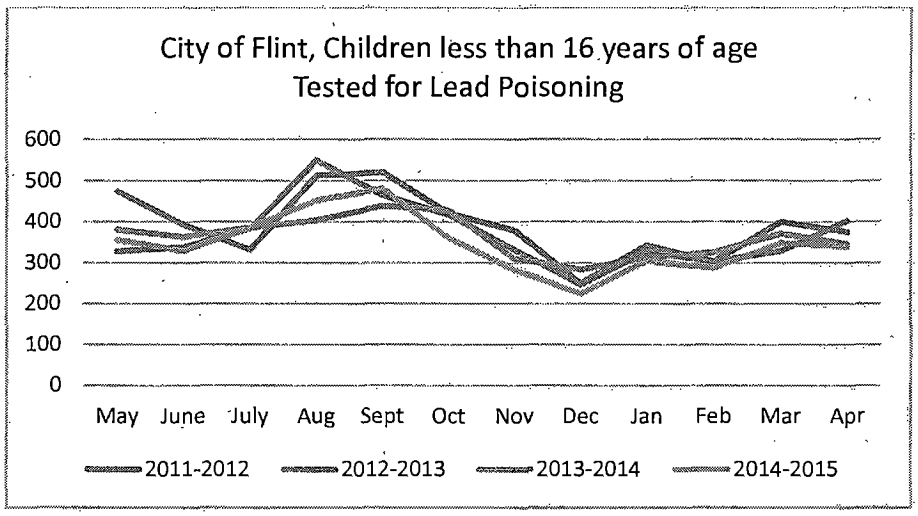
Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Note that the 90th percentile must be interpolated if the number of samples is not a multiple of 10.

7. What was the result of the first round of monitoring conducted by the City?

The first 6-month round of lead and copper monitoring conducted by the City ended on December 31, 2014. One hundred samples were submitted and the 90th percentile lead level was calculated to be 6 ppb. The next step required by the DEQ was for the City to collect a second round of monitoring.

8. What was the result of the second round of monitoring conducted by the City?

The second 6-month round of lead and copper monitoring conducted by the City ended on June 30, 2015. Sixty-nine samples that complied with the site selection criteria were submitted and the 90th percentile lead level was calculated to be 11 ppb. The conclusion from these results was that the City, while in compliance with the action level, exceeded the level required to be deemed as having optimized corrosion control.



9. Why was the City required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of Act 399.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples the City was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census, which listed the City's population as more than 100,000 residents. In March of 2015, the City provided updated information that indicated the City's population had decreased to less than 100,000. Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

- There was a spike in elevated blood lead tests from July-September 2014...

- However, that pattern was not terribly different from what we saw in the previous three years; especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).

- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspected that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

This e-mail from DHHS in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City had not exceeded an action level for lead provided the basis for the DEQ to maintain that the water in the City continued to be in compliance with the federal SDWA and Act 399.

12. When did the DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015, by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." Results indicating elevated lead levels in homes were reported as part of this study in late August. In September 2015, information was reported in news articles that

plant ranges between 55 and 65 mg/l. It should be noted that the City uses ferric chloride as its primary coagulant, although this does not add a significant amount of chloride to the finished water.

4. Has the USEPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by the DEQ?

Yes. On November 3, 2015, the USEPA issued a memorandum regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The USEPA states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation. The memorandum is intended to clarify, on a prospective basis, steps agencies should take or apply in the future. USEPA's new guidance provides acknowledgement that the LCR is subject to differing interpretations. The DEQ's interpretation and application of the LCR in this situation was in compliance with the federal SDWA and Act 399.

5. Did the DEQ reject any of the samples submitted by the City?

Yes, samples at two locations were excluded from the compliance calculation in conformance with rules issued by the USEPA.

According to the LCR, compliance samples must be a first draw, 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted high-risk sampling sites, called Tier 1 sampling sites. For a municipality such as the City, the Tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

As long as a community has Tier 1 sites that contain lead service lines, they are required to collect at least 50 percent of their compliance samples from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point-of-use or point-of-entry treatment can only be used if the community has insufficient Tier 1 sites available.

7. Did the DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The City replaced the lead service line May 6, 2015. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem, and subsequent sampling taken at this address showed that replacement of the service line did mitigate the problem. There was, therefore, no reason to believe that this was indicative of a system-wide problem.

8. Do the DEQ's sampling instructions comply with the LCR?

The DEQ continues to seek official clarification from the USEPA regarding the sampling protocols. The DEQ's sampling recommendations were developed to ensure compliance with the USEPA's guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, the DEQ had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was the USEPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in compliance calculations. Subsequently, the USEPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, the DEQ devised the current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

The DEQ continues to believe it is appropriate to ensure that taps being sampled are representative of typical household use and are sampled during the recommended stagnation period of 6-18 hours. The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. There are a number of other states that share the DEQ's interpretation of the rule and the DEQ encourages the USEPA to provide official clarification directed at all states with primacy.

Summary of Flint Water Date Timeline and Background Information

Overall

- The health and welfare of Flint residents is a top priority and Governor Snyder is committed to a coordinated approach with resources from state agencies to address all aspects of this situation.
- Governor Snyder has requested support from the Federal Emergency Management Agency (FEMA) to coordinate with other federal agencies to provide resources to Flint as we work on short-term and long-term solutions for residents.
- When Governor Snyder became aware that the city of Flint's water showed elevated lead levels and that the state's handling of the situation was being questioned, he requested funding to switch the source back to the Great Lakes Water Authority and appointed an independent task force to identify possible missteps and areas for improvement.
- On Jan. 11 Gov. Snyder created the Flint Water Interagency Coordinating Committee (FWIACC), which will bring together a wide range of experts to work on long-term solutions to the Flint water situation and ongoing public health concerns affecting residents. The FWIACC is made up of experts from government and the Flint community and will set a course of action to remedy the water situation and resulting health issues, and carry on long after the emergency declaration expires.
- The independent Flint Water Task Force is continuing a full review of all local, state and federal actions that led to the current situation in Flint. A detailed report will be released upon completion.

In response to initial findings from the Flint Water Task Force, Governor Rick Snyder accepted the resignation of the Director of the Michigan Department of Environmental Quality.

Here is a summary timeline of the Flint water events:

2006

January: Discussions regarding Karegnondi Water Authority start.

2013

March: Flint City Council votes 7-1 to join the Karengondi Water Authority.

April 16: City of Flint Emergency Manager Ed Kurtz signs agreement to switch from Detroit Water and Sewerage Department water source to KWA. (DWSD) DWSD sets termination of Flint water service for April 17, 2014.

April 17: DWSD said it will stop selling water to the City of Flint in April 2014.

June: Flint notifies the DEQ of intent to operate the Flint Water Treatment Plant full-time using Flint River for drinking water.

2014

Mid-March: City of Flint decides to use the Flint River as a water source.

April: DEQ issues Flint Water Treatment Plant construction permits for full-time operation enhancements.

April 25: City of Flint switches to Flint River water.

July: DEQ begins the first six-month Flint lead-copper monitoring report. Part of EPA corrosion control protocol.

October: GM stops using Flint water because of chloride levels.

December: First round of lead-copper monitoring results come back at 6 ppb.

2015

January 1: DEQ begins second six-month Flint lead/copper monitoring period.

January 12: DWSD offers the City of Flint a waiver of the $4 million reconnection fee to switch back to Detroit water.

February 26: The EPA discusses a resident's water sample testing results with the DEQ. High levels of lead were found in the water at the residence.

February 27: DEQ responded to the EPA saying that the Flint Water Treatment Plant has an optimized corrosion control program.

April 6: Flint proposes installation of Granular Activated Carbon Filter media to reduce disinfection byproducts. This was intended to reduce the discoloration and odor in the water.

April 24: DEQ indicates no corrosion chemical (orthophosphate) in place. DEQ staff ~~thought they~~ were following the EPA protocol for two six month testing periods (to end in July) ~~before it should be put in place~~.

May 28: Sample results from the residence noted with high lead levels on Feb. 26 show lead levels improved after a new copper service line installation.

July 28: Excerpt response from Childhood Lead Poisoning Prevention program head:

"We compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched.

- Lead testing rates remained about the same from year to year
- There was a spike in elevated blood lead tests from July-September 2014
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.
- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015.

"So upon review, we don't believe our data demonstrates an increase in lead poisoning rates that might be attributable to the change in water source for Flint. We recognize that lead exposure via the water is only a small piece of what may be happening for families in Flint, however, we hope the information is helpful."

August 4: Meeting with Governor's Office and Flint pastors.

August 17: DEQ notifies the Flint WTP of the second six-month lead/copper monitoring results that show lead levels at 11 ppb.

August 23: Virginia Tech researcher, Marc Edwards, notifies the DEQ that he will begin a study of the City of Flint water quality.

August 24: Dr. Mona Hanna Attisha from Hurley Hospital contacts Genesee County Health Department for blood lead level data/information.

August 28: Concerned Pastors announce water filter giveaway in Flint.

September 2: Virginia Tech researcher, Marc Edwards, indicates that the corrosiveness of the Flint water is causing lead to leach into the residents' water.

September 24: Hurley Medical Center study issued showing high blood lead levels in City of Flint Children.

September 25: Flint issues lead advisory regarding drinking water

September 29: Dr. Eden Wells, State Medical Officer, contacts Dr. Mona Hanna Attisha regarding her study results.

September 30: Briefing to Director Lyon comparing Lead Copper Rule Testing (EPA protocol) and Marc Edwards protocol.

October 1: Michigan Department of Health and Human Services confirms results of Hurley Medical Center Study.

October 1: MDHHS provides information for Flint Water website, including the following documents: Parent Handbook: Is Your Child Safe From Lead Poisoning, Blood Lead Level Quick Reference for Primary Care Providers, Lead Screening & Testing for Safe, Healthy Michigan Kids, and finally, Pregnant and Nursing Mothers: What You Need to Know.

October 1: City of Flint, Genesee County Health Department urge residents to not drink water and issues "Do Not Drink" Advisory .

October 2: MDHHS determines its study results are now consistent with Hurley findings, Gov. Snyder announces comprehensive action plan to address Flint water issues. State Budget Office approval to use carryover emergency funds and transfer of DEQ funds to purchase water filters.

October 2: Genesee County Health Department school screening water samples collected for analysis.

October 5: MDHHS announces water filters will be available to the public on Oct. 6.

October 7: Flint Technical Advisory Board meets, recommends reconnection to Detroit water.

October 8: Gov. Snyder conducts press conference in Flint, announces plan to reconnect to Detroit water.

October 8: City of Flint develops plan to reconnect to DWSD.

October 15: Gov. Snyder signs bill authorizing funding for Flint to move back to Detroit water system.

October 16: City of Flint reconnects to DWSD.

October 19: DEQ Director Dan Wyant states: "Staff made a mistake while working with the City of Flint. Simply stated, staff employed a federal (corrosion control) protocol they believed was appropriate and it was not."

October 21: Gov. Snyder announces Flint Water Task Force to review state, federal and municipal actions, offer recommendations.

October 28: DEQ issues construction permit for additional corrosion control treatment.

December 9: Flint begins adding supplemental corrosion controls to the water.

December 29: Gov. Snyder takes action on initial findings from Flint Water Task Force.

2016

January 4: Genesee County Commission votes for emergency declaration

January 5: Gov. Snyder declares emergency for Genesee County due to the ongoing health and safety issues caused by lead in the city of Flint's drinking water

- *By declaring a state of emergency, The Governor has made available all state resources in cooperation with local response and recovery operations.*
- *The declaration authorizes the Michigan State Police, Emergency Management and Homeland Security Division (MSP/EMHSD) to coordinate state efforts.*
- *In addition to the emergency declaration, the Governor activated the State Emergency Operations Center to coordinate state departments, the state's response, resources, and relief and recovery activities.*
- *The SEOC is the emergency operations center for the state of Michigan. Located in Lansing, the center is overseen by the MSP/EMHSD and coordinates response and recovery efforts by state agencies and local government. The SEOC is staffed by members of state agencies and other partners for decision making and information coordination during disasters or emergencies in the state of Michigan.*
- *On Jan. 6, the Joint Information Center was opened to lead the state's messaging and information response in coordination with the local Emergency Operations Center, Genesee County, and the City of Flint.*

January 8: Gov. Snyder and Flint Mayor Weaver meet to discuss how city and state can work on water issues.

January 9: MSP Emergency Management Division announces water resource sites established in Flint with bottled water, filters and testing kits

FEMA/National Guard/Resources

- Governor has requested support from FEMA
  - Coordinate interagency recovery plan
  - Identify federal agencies that have programs, authorities, and technical expertise to assist
  - At this point there is not a federal declaration. FEMA is not currently sending supplies to this incident.

- In addition to requesting support from FEMA, the Governor has activated the Michigan National Guard to help our local volunteers distribute supplies at the five water resource sites.
  - The resource sites are open seven days a week from 9 a.m. to 9 p.m. at Flint fire stations.
    - Fire Station #1 310 East 5th St. Flint, MI 48502
    - Fire Station #3 1525 Martin Luther King Ave. Flint, MI 48503
    - Fire Station #5 3402 Western Rd. Flint, MI 48506
    - Fire Station #6 716 West Pierson Rd. Flint, MI 48505
    - Fire Station #8 202 East Atherton Rd. Flint, MI 48507
  - There are water resource teams going door to door to ensure every resident has a water filter and additional water resources
  -
  - Residents who need immediate help should call 211 or the governor's office at 517-335-7858
    - 211 is open 24/7/365
    - To assist the residents of Flint, Governor Snyder's office has committed ensure the constituent relations division will be open 7 days per week from 8 am until 5 pm until further notice.

- The Michigan State Police continue to lead the door to door mission of reaching every Flint resident. They are assisted by the Genesee County Sheriff's office, state of Michigan employees, and volunteers from organizations such as the American Red Cross.
- One of our top priorities is ensuring Flint residents know the resources that are available to them. We have used direct mail, automated calls, emails and bill boards to ensure residents know that information on water resources is available by calling 211 or visiting www.michigan.gov/FlintWater

Additional information

Corrosion Control ~~(From DEQ)~~

- On October 16, 2015 Flint returned to using water supplied by DWSD. The water supplied by DWSD is a finished product ready to use and already has phosphate added to it to assist with corrosion control.

- Recognizing that the level of phosphate in the water from DWSD was designed to be a maintenance dosage, the DEQ and the Flint worked together to bring online supplemental phosphate addition so as to speed up the rebuilding of the protective layer in the distribution system.

- ~~On October 28, 2015 the MDEQ issued a construction permit to Flint for the supplemental corrosion controls.~~

- ~~Flint worked diligently to order and install the necessary equipment and on December 9, 2015 the city began supplemental corrosion controls.~~

- The DEQ is now partnering with Flint, the U.S. EPA and other governmental entities to proactively identify bottlenecks so that the eventual switch from DWSD to the KWA can be done smoothly and with safety being the top priority.

- ~~It is important to note that the water that will be coming from the KWA will have very similar background characteristics as the water currently coming from DWSD.~~

- Even with ~~these~~ similarities between DWSD and KWA water, precautionary measures are being taken.
    - These measures will include running the Flint Water Treatment Plant on a trial basis for a period of time without sending the water into the distribution system so that all of the treatment processes can be thoroughly evaluated.
    - In addition, bench top testing will be conducted to assist in determining how the Water Treatment Plant processes can be optimized.

- The KWA will be supplying raw water. This water will need to be treated by each of the respective water supplies.

- When KWA comes on line, Flint will be receiving raw water that is similar to the raw water that DWSD treats.
    - Flint will then need to operate the water treatment plant for an (as of yet) undetermined period of time.
    - Once Flint has demonstrated that it is capable of generating water with the desired background characteristics it will then be able to then send water to the distribution system.

- For non-Flint residents who want to test their water for lead – they can purchase a testing kit from DEQ for $18 – details follow:
    - Anyone in Michigan who wants to test their water for lead can call the State Drinking Water Lab at 517-335-8184.
    - The lead testing kit costs $18, which includes the sample bottle and instructions shipped to your home as well as the lab test. It does not include the cost of shipping your filled sample bottle back to the lab.
    - Depending on the lab workload, results are typically available within 1-2 weeks.

- Your results will include information about the EPA's lead recommendations as well as contact information for your local health department, which can help you interpret your results further, if needed.

Addressing Flint's Water Concerns

Recent events have raised concerns among many as to the safety and quality of the water provided by the City's utility system. The City is and continues to be committed to assuring that residents and visitors know that the water is safe and that those responsible for providing water are working every day to improve the quality of the water. The quality of the water does need improvement, but that is not to be confused with safety of the water. The recent notice by MDEQ clearly stated that the water provided by the utility system is safe to drink, but cautioned that some vulnerable groups may want to consult with their health care provider if they have concerns. The City remains committed to their efforts to assure that the water is safe for everyone and that quality is both improved and improving.

To date, the City has taken the following actions:

- As an integral part of the transition to the Flint River on a temporary basis, the MDEQ was consulted about the City's plans, and ultimately issued necessary permits to proceed. The City also engaged the services of the LAN engineering firm to guide the city in installing the necessary equipment to treat the water on an ongoing basis. This resulted in the development of a comprehensive drinking water plan.

- The City monitors its water quality on a daily basis to assure that water quality remains within established guidelines. With the variances in water temperature and the leakage and infiltration problems arising as the result of failure of parts of the distribution system, water quality did exceed, for a time, some of the established guidelines. This resulted in the issuance of the recent notices to the public. Upon receipt of information that some guidelines were exceeded, the City's priority focus was to bring water quality back within guidelines. Efforts taken to address non-compliance included increasing water flow through valve replacements and hydrant flushing and optimizing treatment processes.

- The City has committed to increasing communication with the public in order to inform water users factually of the issues which have arisen, to alleviate unnecessary concern and to identify the steps being taken to address the issues. This is being implemented through detailed and easy to understand educational materials being made available both online and at City Hall, as well as through ongoing public informational meetings.

- Most recently, in light of recent concerns raised by resident groups over the quality and safety of water, Department of Public Works Director Howard Croft and his staff collected questions from citizens during a recent public meeting. After reviewing these questions, DPW Director Croft and his staff set out to answer them in concise detail; the result of that work is a full Water System Questions and Answers document is available online. Along with the detailed information within, the document also contains links to other source documents and regulatory statutes found online which were used as reference. **"We want the residents, businesses and visitors of Flint to know that the water in Flint is safe**

and that we are working every day to make improvements to our system to ensure that," said Croft. "Our goal is make sure we get people the information on our efforts and assure them that we are on the right track with them." More documentation, including regular water quality monitoring reports, will be made available.

- Additionally, a number of public meetings have and will continue to take place. Two of the most recent of these took place at the Antioch Baptist Church and the Mott Community College Regional Technology Center. These meetings were held by concerned neighborhood groups and were attended by Mayor Walling and DPW Director Croft. At both meetings, citizens voiced their concerns and asked questions about water quality and the recent violation notice. Director Croft offered detailed answers to common questions, but also offered to investigate specific water issues raised by residents in which the City could offer assistance. Those in attendance came away with a better understanding of the issues surrounding the drinking water in their community.

- The City of Flint will be hosting a water presentation on **Wednesday, January 21, 2015 at 7pm. That presentation will be held in the City Hall Dome** and will feature information detailing water treatment, water distribution and the steps being taken to ensure that citizens get water that meets all regulatory safety and quality standards. City DPW Director Howard Croft and Daugherty Johnson, Utilities Administrator, will be joined on a panel by representatives from the Genesee County Drain Commissioner's office, the Michigan Department of Environmental Quality and LAN engineering. Written questions from the audience will be collected during the presentation and answered by the panel after the presentation.

- The City of Flint has also determined that in light of the serious concerns raised, it will secure the services of an external firm with expertise in managing drinking water quality to assess the steps that the city has taken, to make recommendations as to other steps to be taken, to oversee their implementation, and to monitor operations until the City's water source becomes the KWA. A Request for Proposal was issued on January 15, 2015, with proposals due back on January 26.

The DWSD Question:

As a result of the concerns raised, several community members have suggested that the City reconnect to the Detroit Water and Sewer Department (DWSD). DWSD has advised that they would be willing to allow such a reconnection without a hook-up fee. However, the City would be obligated to pay a fixed monthly charge of $846,700 plus the $14.92/Mcf cost of water itself and agree to a long term arrangement. The City's analysis of the DWSD proposal concludes that the City's cost would increase by more than $12 million per year at the proposed rates, and could increase even more as proposed rates are subject to change after July 1, 2015. This increase in costs would not be in the best interests of the City or its water users, as the City is committed to assuring safety and improving water quality by following its current plan, and reconnecting to DWSD would likely require deferment of existing capital improvements or an additional increase in rates.

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

December 16, 2014

DEQ Resource Management Division
DEC 17 2014
Administration Section

Mr. Brent Wright, Operation Supervisor
City Of Flint - DPW
Flint Water Plant
4500 North Dort Highway
Flint, MI 48505

WSSN: 02310

Dear Mr. Wright:

SUBJECT: Violation Notice – Maximum Contaminant Level for Total Trihalomethanes
Operational Evaluation – Total Trihalomethanes
4th Quarter 2014 Monitoring Period

The Department of Environmental Quality (DEQ), Office of Drinking Water and Municipal Assistance (ODWMA), records show that the City of Flint is in violation of the Safe Drinking Water Act,1976 PA 399, as amended (Act 399); R 325.10610, *Maximum contaminant levels* (MCL) *for disinfection byproducts*, of the 1979 Administrative Code.

In accordance with R.325.10610, *MCLs for disinfection byproducts*, of the 1979 Administrative Code, the MCL for disinfection byproduct total trihalomethanes (TTHM) is 0.080 milligrams per liter (mg/L) as a Locational Running Annual Average (LRAA) at each monitoring location. As listed in the table below, our records show that the City of Flint's highest TTHM locational running annual average (LRAA), based on the last three quarters, ending November 30, 2014, is 0.099 mg/l which exceeds the standard, and that two of the eight sample site locations exceed the standard of 0.080 mg/L.

Further, in accordance with R325.10719l, *Disinfection byproducts: operational evaluation levels*, of the 1979 Administrative Code, when an operational evaluation level (OEL) at a monitoring location for TTHM exceeds 0.080 mg/L, a supply shall conduct an operational evaluation and submit a written report of the evaluation to the department not later than 90 days after being notified of the analytical result that causes the supply to exceed the operational evaluation level. As listed in the table below, our records show that TTHM operational evaluation levels for the City of Flint exceed 0.080 mg/L at four of the City's eight sample site locations.

TTHM Results (mg/L)					
	5/21/14	8/21/14	11/20/14	LRAA	OEL
DBP1 McDonalds 3719 Davison	**0.162**	**0.145**	0.059	**0.092**	**0.106**
DBP2 Liquor Palace 3302 S. Dort Highway	**0.112**	**0.127**	0.033	0.068	0.076
DBP3 North Flint Auto 6204 N. Saginaw St.	**0.097**	**0.118**	0.041	0.064	0.074
DBP4 University Market 2501 Flushing Road	**0.106**	**0.196**	**0.094**	**0.099**	**0.122**
DBP5 Taco Bell 3606 Corunna Road	0.079	**0.181**	0.034	0.074	**0.082**
DBP6 Rite-Aid Pharmacy 5018 Clio Road	**0.088**	**0.144**	0.054	0.072	**0.085**
DBP7 Salem Housing 3216 MLK Boulevard	**0.082**	**0.112**	0.050	0.061	0.074
DBP8 BP Gas Station 822 S. Dort Highway	0.075	**0.112**	0.036	0.056	0.065

Our investigation consisted of a review of ODWMA files for laboratory reports received for compliance monitoring. Our investigation is considered complete. This violation began on December 1, 2014, and will continue until TTHM LRAA is below the MCL at all sample sites.

We acknowledge and appreciate the city's cooperation with our recommendation to preemptively conduct an Operational Evaluation following the City's second quarterly round of monitoring in August. That Operational Evaluation report has identified possible causes and corrective measures for the elevated TTHM levels which we encourage the City continue implementing. These modifications have likely contributed in part to the reduction in TTHM levels reported in the most recent quarter, and suggest the City may be able to achieve compliance with the TTHM standard.

Our office is continuing to review the Operational Evaluation report that was submitted on December 1, 2014, and will provide the City and their consultant comments as needed to help address this MCL violation.

Water systems that exceed the OEL must complete and submit an Operational Evaluation in accordance with Administrative Rule 719l (R325.10719l) within 90 days of being notified of the violation. **An updated Operational Evaluation report, which incorporates the most recent sample results, must now be completed and received by our office by no later than March 1, 2015**.

If you have any other factual information you would like us to consider regarding the violation identified in this Violation Notice (VN), please provide them in a written response by January 16, 2015.

Administrative rule R 325.10403 of Act 399 requires that suppliers provide public notice (PN) as soon as practical, but no later than thirty (30) days after the supplier learns of this type of violation, by mail or direct delivery **and** by any other means reasonably calculated to reach customers not normally reached by mail. Enclosed is a sample PN

which contains the minimum required language. The City is encouraged to include additional information regarding its response to this violation. **Please notify your consumers by January 10, 2015, and send us a signed and dated copy of the notice that you issued within ten (10) days of distributing the public notice.** This violation must also be included in your 2014 Consumer Confidence Report (CCR), due by July 1, 2015. The PN must be repeated every quarter until you no longer exceed the TTHM standard. Failure to issue a PN for this violation will result in a fine of at least $1,000 per event, with a maximum of $5,000 per violation.

We anticipate and appreciate your continued cooperation in resolving this matter. If you have any questions regarding this VN, please contact us at the numbers below.

Sincerely,

Michael F. Prysby, P.E., District Engineer

IMPORTANT INFORMATION ABOUT YOUR DRINKING WATER

City of Flint Did Not Meet Treatment Requirements

Our water system recently violated a drinking water standard. Although this incident was not an emergency, as our customers, you have a right to know what happened and what we are doing to correct this situation.

We routinely monitor for the presence of drinking water contaminants. Samples were collected for total trihalomethanes (TTHM) analysis from eight locations on a quarterly basis (May 21, August 21, and November 20 of 2014). The average of the results at **ANY** of the eight locations must not exceed the maximum contaminant level (MCL) for TTHMs, otherwise our water system exceeds the Maximum Contaminant Level (MCL). The standard for TTHMs is 80 µg/L. The location reporting the highest TTHM level was 99 ug/L; thus, our water system exceeds the TTHM MCL.

What should I do?

- There is nothing you need to do unless you have a severely compromised immune system, have an infant, or are elderly. These people may be at increased risk and should seek advice about drinking water from their health care providers.
- You do not need to boil your water or take other corrective actions. If a situation arises where the water is no longer safe to drink, you will be notified within 24 hours.

What does this mean?

This is not an emergency. If it had been an emergency, you would have been notified within 24 hours.

People who drink water containing trihalomethanes in excess of the MCL over many years may experience problems with their liver, kidneys, or central nervous system, and may have an increased risk of getting cancer.

What is being done?

We are currently working on solutions to correct the problem. We anticipate resolving the problem by 2015.

For more information, please contact Mr. Brent Wright at 517-787-6537 or the Flint Water Plant at 4500 North Dort Highway, Flint, MI 48505.

Please share this information with all the other people who drink this water, especially those who may not have received this notice directly (for example, people in apartments, nursing homes, schools, and businesses). You can do this by posting this notice in a public place or distributing copies by hand or mail.

This notice is being sent to you by the City of Flint.

CERTIFICATION: WSSN: 02310

I certify that this water supply has fully complied with the public notification requirements in the Michigan Safe Drinking Water Act, 1976 PA 399, as amended, and the administrative rules.

Signature	Title	Date Distributed

Reminder to water supplier: This notice / certification must be sent to the DEQ.

State says Flint hasn't applied for permit to use river as drinking water source

A look at Flint water plant's facilities

The city plans to switch over to the Flint River as a primary drinking water source in April. *(MLive.com File Photo)*

FLINT, MI – Not so fast, state officials are telling Flint administrators charging toward an April 18 date to begin using the Flint River for all of the city's water needs.

The Michigan Department of Environmental Quality says it hasn't received the proper paperwork from the city. When the state does get it, a review of the application for state permission to use the river could take 30 to 45 days.

The city is switching over from buying treated water from Detroit to using the Flint River for drinking water temporarily. Once the Karegnondi Water Authority completes its pipeline from Lake Huron to Genesee County, Flint will switch to the KWA.

"In regards to the actual application, we haven't received one," said Steve Busch, Lansing and Jackson district supervisor in the DEQ's office of drinking water and municipal assistance. "We've received preliminary design plans and preliminary specifications and we've commented on those. They may be waiting until they have all the comments worked out before they submit the application."

Flint has bought treated Lake Huron water from Detroit, but that contract was terminated when Flint signed on to purchase 18 million gallons of raw water per day from the Karegnondi Water Authority. The contract termination goes into effect April 17.

The under-construction pipeline will bring raw Lake Huron water to Flint and Genesee County when it is complete by the end of 2016.

People in the city will drink Flint River water until the pipeline is complete. The Detroit Water and Sewerage Department said it would **stop selling water to Flint and Genesee County** on its current contract on April 17, 2014. Genesee County is negotiating with Detroit for water until the KWA pipeline is flowing.

Busch said state reviews generally take between 30 and 45 days, but would not comment on if Flint would be ready to transition to river water by the time Detroit terminates the contract with the city.

"A fully engineered construction package, including all the work to be performed, has been submitted to the DEQ by the city of Flint in preparation for the transition to use of the Flint River as a temporary primary water source," said Howard Croft, Flint's director of public works, in a statement. "The submittal package has been under review for more than 30 days. The city has had ongoing discussions with the DEQ regarding the process and we anticipate a favorable response soon."

If the state hasn't approved Flint's use of river water by April 18, Busch said, the city would just continue to buy water from Detroit on a non-contract price until Flint has state OK to begin using the river.

"I don't think there is any scenario that we will just willy-nilly cut off service for Flint," said Bill Johnson, a consultant and spokesman for Detroit Water and Sewerage Department. "Negotiations are continuing."

Croft said the DEQ has been reviewing the request and asking questions throughout.

"When both sides come to an agreement and all issues have been addressed, then the permit is granted," Croft said in the statement. "Flint has been in ongoing communication with Genesee County and the DWSD to ensure that there is no interruption of water service to Flint customers. As the Mayor (Dayne Walling) said in his State of the City address 'beginning this spring, we will be using treated water from the Flint River as our temporary primary water source.' We are still on target to meet this goal."

Croft said there will be a series of public forums where residents can ask questions about the city's water transition, what that will mean for rates and others. He did not have specifics about when and where those meetings will take place.

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

September 10, 2014

Mr. Brent Wright
City of Flint Water Treatment Plant
4500 North Dort Highway
Flint, Michigan 48505

SUBJECT: Compliance Communication
Total Trihalomethane Operational Evaluation Requested

Under the Stage 2 Disinfectants and Disinfection Byproduct Rule, the City of Flint has been required to collect samples for the analysis of Total Trihalomethane (TTHM) and Haloacetic Acids (HAA5) at eight sites within the City's water distribution system. The City has completed two quarterly monitoring periods since changing its source water to the Flint River effective April 25, 2014.

Normally an Operational Evaluation Level (OEL) would be calculated in accordance with the Michigan Safe Drinking Water Act, Public Act 399, 1976, as amended, Administrative Rule 7196 (R 325.107196), each quarter once three quarters of results have been obtained and compared with the respective maximum contaminant level (MCL) for TTHM. Normally the calculation would be made as follows:

(2 x current quarter + sum of 2 previous quarters) divided by 4

As the City of Flint currently has only two quarters of data, the calculation has been modified as follows:

(2 x current quarter + previous quarter) divided by 4

The resulting OEL for each site is listed in the table below. All results are in parts per billion (ppb):

		TTHM			HAA5	
	5/21/14	8/21/14	Mod. OEL	5/21/14	8/21/14	Mod. OEL
DBP1 McDonalds 3719 Davison	162.4	145.3	113	64	43	38
DBP2 Liquor Palace 822 S. Dort Highway	111.6	112	84	52	40	33
DBP3 North Flint Auto 3302 S. Dort Highway	96.5	127.2	88	48	31	28
DBP4 University Market 3606 Corunna	106.4	181.3	117	55	24	26
DBP5 B&P Gas Station 2501 Flushing	75.1	196.2	117	38	17	18
DBP6 Salem Housing 3216 MLK Boulevard	82.2	112.4	77	41	25	23
DBP7 Kroger 5018 Clio Road	88.2	144.4	94	49	30	27
DBP8 Taco Bell 6204 N. Saginaw	79.2	118.3	79	50	37	31

As shown in the table above, even with this less restrictive modified method, six of the City's eight sites already exceed the OEL limit of 80 ppb for TTHM. In addition, the City's two other sites are both more than 95% of the TTHM OEL limit.

The MCL for TTHM and HAA5 is based on a locational running annual average for each site, essentially the average at each site over the four previous quarterly monitoring periods. However, with TTHM levels of this magnitude, it is likely the MCL will be exceeded for at least one of these eight sites from just three quarters of monitoring results. For TTHM, four quarters at the MCL of 80 ppb (4 x 80) would provide 320 ppb allowable. As an example, site DBP1 through just two quarterly monitoring periods has a total of 307 ppb (162+145), leaving only 13 ppb over two more quarterly monitoring periods to maintain compliance with the MCL.

Therefore, this office is requesting the City of Flint complete an Operational Evaluation in accordance with Administrative Rule 719l (R325.10179l). The Operational Evaluation Report shall be submitted to this office no later than November 28, 2014. The report shall not be limited in scope and shall include the following:

Examination of Treatment Operational Practices
- Changes in source water quality
- Treatment changes
- Storage tank operations
- Excess storage capacity
- Treatment problems that contribute to TTHM formation

Examination of Distribution Operational Practices
- Storage tank operations
- Excess storage capacity
- Distribution system flushing

The report shall also include steps the City could consider to minimize future exceedances.

Additional guidance on completing the Operational Evaluation Report, including a number of forms that can be used to gather and evaluate water system information is provided in the United States Environmental Protection Agency's (U.S. EPA) Operational Evaluation Guidance Manual. This document is available on the U.S. EPA's website at the following link:

http://www.epa.gov/ogwdw/disinfection/stage2/pdfs/draft_guide_stage2_operationalevaluation.pdf

Be advised, failure to submit an Operational Evaluation Report by this deadline is a reporting violation subject to Tier 3 Public Notification.

The OEL is an indicator of operational performance. The water system must take proactive steps to be able to comply with the MCL's for TTHM and HAA5. While it is recognized that removal of Total Organic Carbon disinfection byproduct precursors as part of the treatment process has performed above minimum removal requirements under the treatment technique, around 4 parts per million of organic carbon are still present in the treated water and may be leading to additional TTHM formation in the City's distribution system.

While health effects associated with disinfection byproducts contaminants are based on chronic exposure, the City has available alternatives that must be considered to achieve compliance with this drinking water public health standard.

If you have any questions regarding this information, please contact me at the number below.

Sincerely,

Michael Prysby, P.E.

Subject: DWSD Proposal

Good morning Mr. Kurtz,

Please find attached DWSD's proposal for continued service to Flint and Genesee County. Within the hour I will also send a power point file that provides a summary level presentation of the proposal.
I look forward to answering any questions you may have and supporting the conversation between you and Mr. Orr over the next few days.

April 24, 2013

Ed Kurtz, Emergency Manager
City of Flint
1101 South Saginaw Street
Flint, Michigan

Dear Mr. Kurtz,

I am pleased to offer this Water Supply proposal for continued long-term water supply service to the City of Flint and Genesee County. DWSD is committed to becoming the provider of choice for Water service in Southeast Michigan and looks forward to the opportunity to partner with the City of Flint/Genesee County as the region moves forward. The proposal herein offers Flint the immediate opportunity for a 45% reduction in the cost of water supply saves the Flint/Genesee region over $900 million dollars as compared to the KWA alternative over the 30 year contract period.

On December 20, 1965, the Cities of Detroit and Flint entered into a Water Service Agreement (Agreement) for the City of Detroit Water & Sewerage Department (DWSD) to provide treated water to Flint and for Flint to provide DWSD water to other areas of Genesee County. That Agreement had a 35-year minimum and an indefinite maximum term and is currently in effect. There has been one Amendment to that Agreement dated July 18th, 1990. That amendment addressed a Flint request to reduce the minimum consumption requirement in the agreement by changing "Article 8 (A and B)". This amendment resulted in significantly lower costs to Flint. All other provisions of the Agreement remained unchanged. For over a decade the cities of Detroit and Flint have been in discussions for a successor Water Service Agreement to replace the Agreement currently in place. During the course of those discussions many different service alternatives have been considered but the cities have been unable to agree on terms that would allow their current Agreement to be replaced by a successor water service agreement.

In recent months, via a process largely governed by the State of Michigan, DWSD has proposed a number of alternative approaches for long-term water supply to the Flint/Genesee region. During a meeting with the State on April 19th a process and schedule was outlined that provided DWSD the opportunity to deliver a final proposal to Flint for continued service to the Flint/Genesee region. The proposal herein provides a public/public partnership approach in response to the water service requirements set forth by Flint / Genesee County / KWA as of April 22, 2013 (attached).

The following discussion and exhibits are designed to present the highlights of our submittal, and specifically respond to the points set forth in the request. In summary, our proposal reflects a public/public partnership approach with Flint that is designed to launch a cooperative arrangement toward solving water supply challenges in the Flint/Genesee region in a manner that best meets the interests of Flint and is equitable across the DWSD service area. Our proposed approach is responsive to the specification and has direct benefits to Flint/Genesee. Notably:

- Provides Flint, as partner with a capacity share in the Lake Huron Water Treatment Plant, the advantage of treatment costs calculated from a facility that has a lower cost of production compared to DWSDs other treatment plants; this capacity obligation is secured by a contractual obligation to successors and assigns;
- Effectively negates the distance and elevation factor that exists in the current rate structure to Flint, calculating transmission costs based on the line from the Lake Huron plant to the Baxter/Potter connection;
- Provides redundant (back-up) water supply at the Imlay City Pump Station and reflects fair recognition that Flint will provide a level of "reliability" on its own that DWSD currently provides to other wholesale customers, through construction and ownership of redundant transmission from the Imlay pump station West to Baxter/Potter or other point of connection as determined by Flint further maximizing Flint's interest in ownership of assets.

Highlights of our proposal:

Contract Structure – It is proposed that Flint would enter into a public/public partnership with DWSD that would reflect more input into and control over system investments and cost variables. The contract between Flint and DWSD would include "purchased capacity rights" in the "Lake Huron System" (defined below) based on the specific demands in an Exhibit B to the new contract, presumably the demands would be those included in the specifications attached. This is consistent in nature to DWSD's model contract that has been in place since 2008.

Revenue Requirement Responsibility – Limited to the costs associated with the "Lake Huron System", which includes the Lake Huron Water Treatment Plant and Intake and the transmission, pumping and storage facilities between the Lake Huron Plant and the delivery to Flint at the Baxter/Potter connection. Baseline revenue requirement data (including operating budget, rate of return, etc.) are identical to those developed for all other wholesale customers. No other DWSD costs will be allocable to Flint.

Proposed Rate Structure – Revenue requirements for the Lake Huron System will be recovered through a fixed monthly charge to recover allocated capital revenue requirements, plus a commodity charge to recover annual operating expenses. A separate fixed monthly charge is recovers the allocated "emergency standby" capital revenue requirements.

Redundancy Solution – Emergency backup supply is provided to the Imlay pump station, with the associated standby charge. A second transmission water main from the Imlay City Pumping Station west to either the current connection at Baxter/Potter roads or to another location to be determined by Flint, as necessary to meet the full redundancy requirements specified is assumed for comparison purposes. To maximize Flint's interest in ownership, it is proposed that this line will be constructed by Flint or KWA, and owned and operated by Flint or KWA. No costs associated with this transmission line are included in the proposed rate structure summarized in Exhibit 1. For the purposes of comparison of alternatives we have included an estimated annual revenue requirement for constructing such line, and these costs are reflected in the projections summarized in Exhibits 2 and 3. The costs for the second line included herein are consistent with those identified by TYJT in a follow-on effort to their report dated February 2013 on the

"twinned" line approach. Should Flint decide that it is not their preference to own this new transmission line, DWSD is receptive to other approaches, including DWSD financing and ownership.

Representation on the DWSD Board of Commissioners – DWSD is receptive to this concept and will pursue modification of the current governance structure to accommodate it.

Rate Increase "Guarantee" - DWSD proposes a guarantee that the capital portion of the Lake Huron System rate structure (the fixed monthly charge) will not increase for the life of the contract, unless additional capital investment is made in current and future Lake Huron System facilities. The only project in the current Capital Improvement Plan for the Lake Huron System is replacement of one low lift pump that is included in the fixed cost calculation. (Throughout this proposal the O&M escalation for the various revenue requirements are consistent with those applied in the TYJT evaluation conducted for the state.) In addition to the governance representation noted above and additionally through contractual treatment as a "partner" in a Lake Huron Operating Committee (proposed to have two Flint representatives and two DWSD representatives) Flint will have a level of control of such investments, and therefore a level of control over future capital revenue requirements included in the Flint rate structure. At Flint's option, an independent audit of the Lake Huron System costs can be requested annually and conducted by a mutually agreed upon firm and at a mutually agreeable cost.

Capacity - Flint will be entering a unique partnering agreement, initially purchasing capacity rights of 40 MGD in the Lake Huron Facility. The initial contract capacity would be set at 40 MGD per the specification. In addition, the contract will provide a reopener process every five years during which KWA may increase the contracted demands. DWSD will then allocate costs to Flint based on the new capacity requirement in the same manner as the initial allocation. This provision will accommodate potential growth in the KWA region without requiring Flint to encumber the full cost of projected future demands in early stages of the contract.

Proposed Rate Calculation

The annual revenue requirements are calculated (using FY 2013-14 as the baseline) as those that are allocable to the Lake Huron System. For purposes of this proposal, the Lake Huron System is defined as including:

- The Lake Huron Water Treatment Plant and related structures (intake, etc.)
- The 120" water main from the Lake Huron Plant to the Imlay City Pumping Station
- The Imlay City Pumping Station and related structures (reservoir, etc.)
- The 72" main from the Imlay City Pumping Station to the connection to Flint at Baxter/Potter Road

The Flint relative shares of the allocated Lake Huron System revenue requirement are based on the specifications provided by Flint. Capital costs have been allocated based on relative max day demands (for the plant) and peak hour demands (for the transmission facilities). Operation and Maintenance expenses have been allocated based on relative average day demands for all facilities.

The rate structure proposed herein recovers the allocated FY 2013-14 revenue requirements. All capital revenue requirements are proposed to be recovered through a fixed monthly charge. All operation and maintenance revenue requirements are proposed to be recoverable through a commodity rate applied to actual water purchases. An "average unit cost" per Mcf has been calculated based on the specification provided to illustrate the total revenue requirement expressed as a unit cost of projected water sales.

The analytical results of the proposal are illustrated in the attached table (Exhibit 1). Page 1 of this table shows the calculation of the proposed rate structure for FY 2013-14. As mentioned above, the fixed monthly charge associated with current capital costs of the Lake Huron System (shown on Line 1) will never increase so long as the purchased capacity requirement stays constant. Changes to the fixed monthly charge can increase only with (a) additional purchased capacity through the contract re-opener process (permissive to Flint), or (b) additional investment in Lake Huron System facilities for which Flint has both partnership input at the operating committee level and governance representation on the Board.

Page 2 of Exhibit 1 provides background to the rate structure calculation and illustrates the allocation of FY 2013-14 revenue requirements associated with the Lake Huron System facilities to Flint based on the contract demands set forth in the specifications document. It also illustrates the calculation of the emergency standby charge. This charge is designed to reflect the reservation of one day's worth of average daily capacity in the portions of the DWSD "backbone" (treatment and major transmission) system from which Flint will not receive "regular" service - and in which it will not be a "partner".

TYJT's report on the City of Flint Water Supply Assessment from February of this year included a number of tables and charts that compare revenue requirements to Flint under various alternatives. Attached herein is an updated Table 6.1 (Exhibit 2) which compares the cumulative annual cost of each option from the TYJT report with the new proposal included. We've also included an Exhibit 3 which is similar in format to Figure 6.1 in the TYJT report. However the data in this exhibit is a bit more inclusive, as it accumulates ALL of the annual utility costs for the KWA service area. DWSD submits that these exhibits illustrate the comparative advantage of DWSD's current proposal to the KWA proposal, and demonstrate the significant cost advantage provided with the innovative public/public partnership approach we are proposing.

In the nature of an executive summary or overview, we have submitted a companion power point presentation that calls out many of the significant features of this proposal. This is firm offer that is available with the rate season beginning July 1, 2014, however we remain open to discussion and negotiation.

Best regards,

Sue McCormick, Director
Detroit Water & Sewerage Department

Specification Sheet for Evaluating Water Service Options to Flint and/or KWA/Genesee County (KWA/GC) Service Area

Issued: April 22, 2013

Purpose: The purpose of this document is to 1) clarify the water service requirements so that DWSD may submit a proposal responsive to the current requirements of Flint and/or KWA/GC and 2) provide a framework for a comparable and equitable analysis of water service proposals from DWSD, KWA/GC, and/or any other parties.

- **Scope:** DWSD's proposal will be evaluated based on water service delivery to(select one):

  Flint only **or** Flint and KWA/GCC

2. **Objectives:** Identify the outcomes and criteria that serve as the basis for evaluating water service based on the scope defined in Q. 1 above.

- **Maintain current supply standards**
- **Reduce our cost share of DWSD system we don't use**
- **Stabilize rate**
- **Increase control over cost variables (be an owner, not a user)**
- **Redundant service at Baxter Potter**

3A. Treated Water Capacity Worksheet (5 Year Increments 2013-2042)

		2013	2018	2023	2028	2032	2037	2042
	Flint							
	Pressure Range							
	Max Day(MGD)							
	Peak Hour(MGD)							
	Avg Day (MGD)							
	KWA/GC							
	Pressure Range	**50 PSI Winter 65 PSI Summer**						
	Max Day(MGD)	**40**	**43**	**47**	**50**	**53**	**57**	**60**
	Peak Hour(MGD)	**44**	**47**	**52**	**55**	**58**	**63**	**66**

	Total							
	Pressure Range							
	Max Day(MGD)							
	Peak Hour(MGD)							
	Avg Day (MGD)							

3B. Raw Water (End Use) Capacity Worksheet (5 Year Increments 2013-2042) in excess of the specified treated water requirements

		2013	2018	2023	2028	2032	2037	2042
	Flint							
	Pressure Range							
	Max Day(MGD)							
	Peak Hour(MGD)							
	Avg Day (MGD)							
	KWA/GC							
	Pressure Range	0						
	Max Day(MGD)	0						
	Peak Hour(MGD)	0						
	Avg Day (MGD)	0						
	Total							
	Pressure Range	0						
	Max Day(MGD)	0						
	Peak Hour(MGD)	0						
	Avg Day (MGD)	0						

4. **Provide Redundancy/Reliability alternatives for Treated Water?** Circle yes or no for each

For Flint: Yes or No For KWA/GC **Yes**

Option 1 -Full redundancy-2nd source (specify delivery point)

--Baxter Potter or second point into Genesee County

Option 2 – Redundancy via storage (specify location point and volume)

--Not Applicable

5. **Permission to blend?** **No**

If Yes, specify any operating requirements/limitations to blending.

6. **Representation:**

On DWSD Board? **Yes**

On DWSD Operating Committee? **Yes**

7. **Capital Costs:** Capital improvements/upgrades requested to achieve water service objectives.

--See No. 4

8. **Pricing:** Cost of service based on a rate model specific to named facilities and auditable account structure.

Alternative 1: **Annual rate** proposed based on budget and estimated usage, billed monthly based on metered usage.
Electable option: Subject to annual audit and true up in the next full rate year after close of audit. **NA**

Alternative 2: Annual fixed amount proposed based on budget and estimated usage; billed monthly in 12 equal monthly bills. Subject to annual audit and true up in the next full rate year after close of audit. **NA**

Alternative 3: Customer specified pricing requirement(s)
- Redundant service as a separate fixed rate

- Annual fixed amount with a commodity charge based on service from Port Huron and pipeline only.

- Capital cost and O & M for Port Huron operations only

9. **Other Criteria:** Identify any other criteria or materials that DWSD should provide for an objective evaluation of DWSD provided service compared to non-DWSD options.

- All current and future costs not to increase by more than 4.7% annually over the life of the contract

Flint residents should be drinking Flint River water by mid-April, officials say

on March 12, 2014 at 6:10 PM, updated March 12, 2014 at 6:13 PM

FLINT, MI – If all goes as planned, Flint residents will have Flint River water flowing from their taps by mid-April.

Flint city leaders and Flint Water Treatment Plant officials held a ceremonial groundbreaking Wednesday, March 12, to mark the start of the process of drawing water from the Flint River.

"This is an important day for us as we break ground on this new project in the city of Flint," said Flint Mayor Dayne Walling. "The river is an invaluable asset."

The city has bought its water from Detroit, but that contract was terminated when Flint signed on to purchase 18 million gallons of raw water per day from the Karegnondi Water Authority.

The under-construction pipeline will bring raw Lake Huron water to Flint and Genesee County when it is complete by the end of 2016.

People in the city will drink Flint River water until the pipeline is complete. Detroit Water and Sewerage Department Director **said it would stop selling water to Flint and Genesee County on April 17, 2014.**

In the next couple of weeks, six more employees will be hired to help keep the water treatment plant better staffed as it is used to its full capacity. After the new hires are on board, there will be a total of 26 employees with at least four employees working at any given time, compared to the one on duty now.

The plant, which is used as a backup water supply to Flint and Genesee County, will go from being used four times a year to year-round.

Work will also take place within the next two weeks to update the electrical system from the 1950's, said Brent Wright, plant superintendent.

After Detroit cancelled its water contract here, **Flint has spent about $4 million in upgrades at the water treatment plant in the past eight months.**

"What we're doing with the upgrade is increasing reliability," said Daugherty Johnson, utilities administrator at the water treatment plant.

The treatment plant could easily be used now if it had to be used, Wright said. There is 55 million gallons of water already in storage. But the process now is to make sure the plant is well staffed and updated to handle the greater use, Wright said.

In the next year, a small pump lift station will also be built.

"This is a tremendous step in the process of securing Flint's water future," Walling said.

When it's time to switch over, the process should be smooth and effortless, Wright said. Before the switch is complete, the Flint water treatment plant will already be fully operational, testing the process a couple weeks before the process is complete.

Then once they are ready to go, plant officials will simply turn off the switch for the 72-inch pipeline from Detroit and turn on the switch for the 36inch pipeline that will draw in water from a location in the Flint River near the plant.

The target date for the switch is mid-April. On average, the plant will see 12 million gallons of water going through daily.

When Wright started working at the plant 23 years ago, he was told they would be starting the process to no longer purchase water from Detroit. And now it's happening.

"We're finally doing it. And I get to see it," Wright said.

Sam Muma, president of AFSCME Local 1600, said it's good to see the plant being used to its full potential and for the river to be utilized to its full potential.

In all, the upgrades and further use of the water treatment plant will be a benefit to the community, Muma said.

"This is a good thing for the community. It will provide jobs," Muma said. "Anytime you can be self-sufficient is a good thing. Doing this should eventually decrease water rates for the residents in Flint."

The long-term goal is to have more water efficiency and more cost savings in water rates.

The hope is to also bring school children out to the plant to have educational tours.

"Today marks the beginning of the new narrative of the city of Flint," said Flint's Director of Public Works Howard Croft.

City says Flint River water will be pumped to homes, businesses Monday, April 21

Ron Fonger | rfonger1@mlive.com By **Ron Fonger | rfonger1@mlive.com**
on April 17, 2014 at 11:00 AM, updated April 17, 2014 at 12:30 PM

FLINT, MI -- Faucets in the city will be filled with **Flint River water** starting Monday, April 21, officials said today, April 17.

Flint emergency manager Darnell Earley speaks at a news conference today, April 17, inside Flint City Hall.

Ron Fonger | MLive.com

Emergency Manager Darnell Earley and city public works officials said they plan to open gates at the Flint water treatment plant at 2 p.m. today, bringing in about 12 million gallons of river water for treatment test runs that are expected to continue throughout the weekend.

That step will mark the beginning of the end of nearly 50 years of Flint's reliance on the city of Detroit for its water.

Representatives with the state Department of Environmental Quality are expected to be here Friday, April 18, to ensure that treatment plant upgrades they have issued permits for have been completed.

If all goes according to plan, a mix of river water and residual Lake Huron water will flow into homes and businesses Monday, and officials said they don't expect customers to notice a difference -- in pressure, appearance or taste -- from what they are drinking now.

"We're proceeding as planned," Earley said. "I'm very pleased ... We have the opportunity to use the natural resources of the river ... We have a better mechanism to manage our costs. It's strictly our product now."

Although Flint River water has been used in emergency situations and treated quarterly before being discharged back to the river, Monday will be different.

"This time, we do not intend to stop drawing the water in until the (Karegnondi Water Authority) pipeline is completed," said Howard Croft, Flint's public works director.

"We believe that on Monday, we will be in a position to close the valve to Detroit," Croft said.

Today's announcement by city officials comes on the day after the city of Detroit terminated its contract to sell water to Flint and Genesee County under the terms of an expired contract and instituted a new price structure, adding what amounts to a surcharge of about 10 percent.

Most public water customers in Genesee County, outside the city of Flint, will continue to receive Lake Huron water purchased from the city of Detroit by the county Drain Commissioner's Office and resold by cities and townships to home and business customers.

The city and county have formed the KWA to fund a $600-million pipeline project designed to supply the region's water for decades. Construction on that massive public works project is underway and is expected to be completed by the close of 2016.

Follow our live blog today when Flint residents can learn more about the city's water source and what future water rates could be during **two meetings today**.

A forum for Flint restaurateurs is scheduled for 3 p.m. inside Café Rhema, 432 S. Saginaw St., and will allow local managers and owners to address questions about the new water source.

The second meeting will be an informational presentation in the council chambers at Flint City Hall at 5:30 p.m. and will allow residents to ask questions about a study from Raftelis Financial Consultants, Inc., which recommended a $52.56 annual increase to water and sewer rates for the average residential customer in 2015.

Subject: RE: AGENDA for Today's Call on Flint

Thanks Tinka.

During discussion issue #1, we would like to discuss our (hopefully, mutual) understanding of the timeline for next steps.

Also, while we understand your concerns with the overall implementation of the lead and copper rule(s); we think it is appropriate for EPA to indicate in writing (an e-mail would be sufficient) your concurrence that the city is in compliance with the lead and copper rule as implemented in Michigan. This would help distinguish between our goals to address important public health issues separately from the compliance requirements of the actual rule which we believe have been and continue to be met in the city of Flint.

And finally, we would also like to discuss our concern that the draft report was released by EPA and that we (DEQ) obtained a copy of the report from an outside (ACLU) website.

Notes on Call with MDEQ on July 21, 2015

MDEQ Implementation of LCR Rule and Flint Issues

Issue #1: Is there a public health concern regarding lead in Flint or other regulatory requirements?

- The 90th percentile results of the 2nd round of monitoring was 11 ppb.
- The population has dropped to under 100,000 and therefore the 1st round of 6-month monitoring was done for 100 samples, but the 2nd round only needed 60 samples.
- Customer-requested samples were included, but MDEQ did not have specifics on how many there were.
- Tinka asked about the timeline for Flint to switch over to the Lake Huron water source. MDEQ said the pipeline is under construction and scheduled to be complete by July 2016. MDEQ expects some delays and thinks a more realistic timeframe is October 2016.
- MDEQ explained that Flint would have 18 months to complete the corrosion control study and the complicating factor of switching over to Lake Huron. Should the corrosion control study be based on the Lake Huron source? MDEQ also explained that once Flint is using Lake Huron water that they would then need to complete 2 more rounds of 6-month monitoring to assess whether any adjustments to the corrosion control treatment was needed.
- MDEQ will be sending a letter to Flint telling them they need to complete a corrosion control study – based on results they are not optimized. Given the timing of completing a corrosion control study and the anticipated switch to Lake Huron water, MDEQ will have discussions with Flint and request that they start corrosion control treatment as soon as possible.
- MDEQ asked for Region 5's opinion on whether the regulations allow for the study requirement for Flint to be waived if MDEQ has Flint start pH adjustments and adding phosphates. Region 5 will look into this and get back to MDEQ with an answer. All acknowledged that if Flint initiated corrosion control treatment and continued to evaluate the system to ensure optimization that these efforts would essentially equate to a corrosion control study.
- The Region raised its concern about looking at treatment more comprehensively to ensure problems with DBPs didn't occur. MDEQ stated that Flint is on the brink of DBP compliance and that bacteriological issues haven't occurred since last year. Any adjustments for corrosion control treatment would need to make sure the other issues weren't exacerbated.
- Region 5 again offered the assistance of ORD staff, Darren Lytle and Mike Schock which MDEQ said they had shared with Flint already.

Issue #2: Discuss optimal corrosion control requirements

Discussion Items:

- MDEQ explained that they did not treat the switch to Flint River water as a "new system", but as a new source. It is their understanding that 2 rounds of 6-month monitoring is still needed to characterize the water quality. They don't know what is optimized until those 2 rounds of 6-month monitoring are completed.

DRAFT

- Region 5 noted that under 141.81(b)(3)(iii) that any system that has been deemed optimized must notify the State of any long-term change in treatment or the addition of a new source. The State must review and approve the change and may require any such system to conduct additional monitoring or other action to ensure that the system maintains minimal levels of corrosion in the distribution system. The State's requirement for 2 additional rounds of 6-month monitoring would fall under the "additional monitoring" prescribed by the State and not the initial 2 rounds of 6-month monitoring for new systems.
- Region 5 explained that they have talked to HQ about the interpretation of regulations and believes that systems that have been deemed optimized need to "maintain" corrosion control. The Region agreed to provide supporting regulatory citations for the language about maintaining corrosion control. Ed Moriarty in OGWDW is also consulting OGC on this topic and the OGC opinion will also be shared.
- MDEQ mentioned that there are other communities that may leave the Detroit system or connect to the new Lake Huron pipeline, but many of those either don't need to treat for corrosion control or will be building new treatment plants. Requirements for maintaining corrosion control for additional communities connecting to the Lake Huron pipeline will be discussed further after receipt of the HQ/OGC opinion.

Issue #3: Discuss Pre-flushing (as time allows)

- Lead compliance sampling procedures in the state of Michigan comply with Federal SDWA requirements which calls for a minimum of 6 hours during which there is no water used from the tap the sample is taken from.
- MDEQ is not interested in changing its position on pre-flushing until new regulations come out. They also pointed out that the pre-flushing instructions are not requirements, but suggestions.
- The Michigan pre-flushing instructions were developed as a way to ensure that sampled faucets were not stagnant for an excessive period of time beyond the targeted 6 hour (i.e., rarely used faucets or when a homeowner has been gone for an extended period of time).

Next Steps:

- **MDEQ will send a letter to Flint regarding the 2 rounds of 6-month monitoring results that exceed 5 ppb and the need for a corrosion control study. They will have discussions with Flint to request that they start corrosion control treatment as soon as possible rather than waiting for the completion of a study that can take 18 months.**
- **MDEQ and the Region were in agreement that it is important to get phosphate addition going in Flint as soon as possible. MDEQ mentioned tapping Mike Shock for help with this in the interim.**
- **Region 5 commented that we now have a path forward for Flint despite a difference of opinion on whether the regulations required Flint to "maintain" corrosion control treatment when they started serving treated water from the Flint River.**
- **MDEQ and Region 5 agreed that after Flint implements corrosion control treatment, when they switch back to Lake Huron water, they will need to continue the corrosion control treatment while conducting monitoring to determine if this treatment is optimized with the new Lake Huron water quality.**

DRAFT

- Region 5 will get back to MDEQ once it gets HQ/OGC's opinion on the need to "maintain" corrosion control treatment once a system is deemed optimized.
- MDEQ and Region 5 agreed that other communities currently implementing corrosion control treatment and change sources will need to continue to provide corrosion control treatment and conduct monitoring to determine whether the treatment is optimized with the new source water quality.
- Region 5 will research and get back to MDEQ on the 141.81 (3)(b)(5) citation and the ability to waive a CCT study.

DRAFT

Subject: RE: Lake Huron Intake Project

Hi Steve,

Regarding your questions,

1. The County plans to provide the ability to back flush the intake; however, these provisions are planned to be incorporated into the pump station piping design. Having two intake cribs will enable us to supply water in the event one is damaged by a boat collision or lost by icing.
2. We don't believe that corrosion of the hardware will be a problem. Underwater, there is typically less available oxygen so corrosion occurs very slowly. Warren Green indicated that a recent video inspection of the Saginaw-Midland intakes showed that the hardware was in good condition. One intake was installed in 1947 and the other in 1994. Warren indicated that hardware on the 1994 intake still has paint on it. The paint specified for our project is a high quality 2 part epoxy. Also, the design for the crib is based on 20% of the strength of the hardware, so substantial loss by corrosion would be needed before there will be an impact to the integrity of the crib.
3. There is a reference in the specification regarding how the timber is to be grade-stamped if the timber will be stained or visible, but we will not be putting a coating or stain on the timber.

If there are other questions, please let me know. Thanks.

Subject: RE: Lake Huron Intake Project

Jim,

I have completed my review of the Lake Huron Water Supply Initiative Intake design and Junction Chamber. I have the following questions:

1. The top of crib 1 is 10 to 12 feet below the water surface. The top of crib 2 is 16 to 18 feet below the water surface. This raises two concerns. The first concern for crib 1 one is whether larger boats will run into the crib. The second concern for both cribs is whether both will plug with frazil ice at the same time. Question: Does the design include intake back flush capability?
2. Specification section 05550, "Bolts, Anchor Bolts, Expansion Anchors, and Concrete Inserts" indicates that submerged non-stainless steel metal parts will receive epoxy coating at a minimum. I am concerned that these coatings will not last 50 years. What is your opinion?
3. Specification section 06130 "Heavy Timber Construction" indicates that the timber on the intake will be stained or have a natural finish applied. Are these finishes NSF approved?

Please respond in writing. If we need to talk prior to the written response, give me a call.

Steve,
Attached are two specifications which I did not include in the permit application package.

- Section 05550 Bolts, Anchor Bolts, Expansion Anchors, and Concrete Inserts
- Section 06130 Heavy Timber Construction

These describe the materials used to construct the intake cribs.
Let me know if there are questions. Thanks.

CITY OF FLINT WTP
TTHM Response Plan Meeting Minutes
Notes from the meeting shown in red, bold font
November 7, 2014 9:30 am

Discussion Topics

I. Introductions

II. Purpose/Overview

WG provided an historical review of Flint WTP since ~1999 through today including design and regulatory concerns. Phase I improvements from 1999-2005 were completed to allow the plant to operate as an emergency back-up to DWSD supply for a moderate time period (4-6 weeks). Phase II improvements are defined as improvements to allow the plant to operate full time, without DWSD supply. The ultimate supply will be Lake Huron water supplied through the KWA system. The Flint River is the current supply until KWA supply is available. A treatability study was completed in 2002 which evaluated full time supply from the Flint River and contains information that is directly relevant to today's operations.

A. KWA supply timing
   1. Expected completion fall 2016
B. TTHM high level samples
C. Levels at multiple sites indicate source / WTP issue
   1. Problem did not exist on Detroit water
   2. 8 sites likely to exceed OEL

III. Suspected Causes
   A. Source water
      1. TOC has remained consistent
      2. Turbidity has remained consistent
      3. pH has remained consistent
      4. Increase in total Coliform

Period	Turbidity NTU	TOC Mg/l	Alkalinity Mg/l	Hardness Mg/l	pH	Total Col. Count/day
2001 Apr–Oct	7.9	9.4	215	272	8.1	870-1230 (7300 max)
2014 May–Sept	8.1	10.3 5/22/14	205	250	8.1	1500-5000 (22,398 max)

   B. WTP operation
      1. Ozone feed not working properly
      2. Recent increased chlorine feed
      3. Coag or floc polymer aids might not be optimized
   C. Distribution problems
      1. Low flow
      2. Dead ends
      3. Too much storage
      4. **City has unlined CI**
      5. **Cedar Street and West Side pump stations do not pump into defined pressure districts and may be recirculating water**

6. **City has been repairing/replacing valves which could be resulting in flow pattern changes**

IV. Operational Evaluation Report Requirements
   A. Distribution system evaluation
      1. Distribution evaluation and modeling by others
      2. Storage capacity evaluation
      3. **The City is considering water model updates and new simulations to evaluate possible improvements**

   B. Source water evaluation
   C. Treatment evaluation
      1. Jar testing
      2. No ozone piloting
      3. Experiment with coag and floc polymer aid dosages
   D. Timing / schedule

Letter from MDEQ states the report is to be submitted by 11/28/14. However, regulations state the public water supply has 90 days from the date of violation to complete the Operational Evaluation Report and Flint has technically not had a violation yet. The next sampling period is the 3rd week of November. SB stated the MDEQ would like to have a draft report by 11/28/14 that would not need to be entirely complete, but this would show a proactive approach by the City.

V. Possible Solutions
   A. Chlorine dioxide or chloramine

LAN believes there is a reasonable chance that chloramine would not be a strong enough disinfectanct but chlorine dioxide warrants further consideration.

   B. Decreased chlorine feed rate

A portion of flow through the WTP was being bypassed around the softening process and it was believed to be contributing to chlorine demand. The City has discontinued the bypass and it appears chlorine demand has dropped by 0.5 – 1.0 mg/l.

   C. pH adjustment
   D. Corrections/modifications to ozone

The City and LAN have looked at the ozone feed system and data suggests there is a problem though the exact issue is yet to be determined. Further investigation is planned as one high priority response.

   E. Coag & floc polymer aids (better TOC removal)

Jar testing is planned as part of the OER during which polymer aids will be further evaluated.

   F. Enhanced TOC removal with softening
   G. UV??? [with chlorine after for residual]
   H. Flushing to decrease water age?

The City is considering increased flushing to address both water age and rusty water.

   I. Lower storage tank high water levels (use less volume)?

VI. Other

- Chlorine demand through the filters is another concern. The City may shock the filters with high chlorine feed in an attempt to 'cleanse' them.
- Addition of flocculation and/or coagulation polymer feeds: MDEQ is open to the idea and would consider a letter submittal from the City listing the details in order to provide approval if the City wants to implement into the WTP process.
- The average flow through the WTP has fallen off from 18-19 mgd over the summer to ~14 mgd at this time.
- A TTHM limit violation is Tier 2 and will require the appropriate public notice.
- The City is currently achieving ~60% TOC removal.
- pH is currently 7.5-8.0 at WTP effluent.
- Costs to reconnect to DWSD supply have become prohibitive as a viable solution: $4 Million start up fee + $900,000 monthly flat fee + usage charges.
-

DEPARTMENT OF ENVIRONMENTAL QUALITY

GOVERNOR'S OFFICE BRIEFING PAPER
CITY OF FLINT DRINKING WATER

What contributed to the Boil Water Advisories in the city of Flint?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWAs) in the city of Flint during August and September 2014. While use of the Flint River has increased the amount of natural organic matter in the city's water, the Flint Water Treatment Plant (WTP) has performed well above treatment requirements for organic carbon removal. In addition, less than 20 percent of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the city, rather than in such a localized area.

The city's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the city's over 550 miles of water mains are now over 75 years old and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior, leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The city has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses, and industrial property. Declining water use leads to excess residence time within the city's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the city has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The city, which historically has unaccounted water losses of over 30 percent, has seen even greater losses since February 2014 due to an increase in cold weather-related water main breaks and leaks. The city lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWAs were found to be closed during the city's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure. One of these valves has remained broken.

The BWAs also occurred during the warmest and, for 2014, relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

Process for Issuance and Cancelation of a Boil Water Advisory

There are a number of conditions that can trigger BWAs. This includes the following:

- Bacteria Monitoring Detections
- Bacteria Standards Violations
- Treatment System Failures
- Waterborne Disease Outbreaks
- Loss of System Pressure
- Water Main Breaks
- Other Interruptions in Service

The Department of Environmental Quality (DEQ) has developed a policy and procedure regarding BWAs to help guide staff, provide consistency, and maintain public health. A PDF of Policy and Procedure No. ODWMA-399-022 is being forwarded with this briefing paper.

BWAs may be self-initiated by the water system, issued collaboratively in consultation with the DEQ, or when necessary mandated by the DEQ. Requesting customers to boil the water when bacterial contamination has occurred provides an added barrier of public health protection.

The BWAs that recently occurred in the city of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the city of Flint collaboratively in consultation with the DEQ.

Current regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the U.S. Environmental Protection Agency, have been in effect since 1990, and were incorporated into the Michigan Safe Drinking Water Act, 1976 PA 399, as amended. There are a variety of bacteria, parasites, and viruses that can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for total coliform and *E.coli*. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system minimizes the likelihood that pathogens are present. *E.coli* is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for a period of 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

Recent History of the City of Flint Water System

Historically, the city of Flint had been a customer of the Detroit Water and Sewerage Department (DWSD) while simultaneously maintaining the Flint WTP to provide emergency backup service using the Flint River. The WTP performed quarterly test operations to maintain readiness and was utilized twice in 2009, supplying water once for 2 days and the other for 3 days.

In April 2013 the city of Flint notified the DWSD that it would be terminating service in the future and contracting for raw water service from the Karegnondi Water Authority (KWA). Work on the KWA pipeline from Lake Huron broke ground in June 2013 and is expected to be completed with connection in late 2016.

In August 2013 Rowe Professional Services Company completed an engineering proposal for improvements to the Flint WTP that would allow continuous operation of the WTP utilizing the Flint River in lieu of continuing service from the DWSD until completion of the KWA pipeline. In March 2014 the city of Flint entered into a Consent Agreement with the DEQ regarding the Flint WTP's lime sludge facility. In April 2014 the DEQ issued a construction permit for improvements to the Flint WTP. On April 25, 2014, the city of Flint began continuous operation of the WTP, using water from the Flint River and discontinued the purchase of water from the DWSD.

A BWA was issued for August 15-20, 2014, for a portion of the city of Flint due to localized detections of total coliform and *E.coli* bacteria. Another BWA was issued for September 5-9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the city of Flint. The advisory covered an area of approximately six square miles. The city of Flint has a total land area of just over 34 square miles.

While many of the BWA contributing factors listed above require long-term solutions, the city has taken operational steps to limit the potential for a BWA to reoccur. The city has increased flushing of water mains to limit residence time, maintain disinfectant residual, and help remove buildup and deposits within the piping. The city is boosting chlorine disinfectant residual at locations in the distribution system as needed. The city continues to investigate water leaks and water main breaks and the status and condition of system valves.

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

September 10, 2014

Mr. Brent Wright
City of Flint Water Treatment Plant
4500 North Dort Highway
Flint, Michigan 48505

9/10/14
TTHM OEL
Exceeds MCL

SUBJECT: Compliance Communication
Total Trihalomethane Operational Evaluation Requested

Under the Stage 2 Disinfectants and Disinfection Byproduct Rule, the City of Flint has been required to collect samples for the analysis of Total Trihalomethane (TTHM) and Haloacetic Acids (HAA5) at eight sites within the City's water distribution system. The City has completed two quarterly monitoring periods since changing its source water to the Flint River effective April 25, 2014.

Normally an Operational Evaluation Level (OEL) would be calculated in accordance with the Michigan Safe Drinking Water Act, Public Act 399, 1976, as amended, Administrative Rule 7196 (R 325.107196), each quarter once three quarters of results have been obtained and compared with the respective maximum contaminant level (MCL) for TTHM. Normally the calculation would be made as follows:

(2 x current quarter + sum of 2 previous quarters) divided by 4

As the City of Flint currently has only two quarters of data, the calculation has been modified as follows:

(2 x current quarter + previous quarter) divided by 4

The resulting OEL for each site is listed in the table below. All results are in parts per billion (ppb):

	TTHM			HAA5		
	5/21/14	8/21/14	Mod. OEL	5/21/14	8/21/14	Mod. OEL
DBP1 McDonalds 3719 Davison	162.4	145.3	113	64	43	38
DBP2 Liquor Palace 822 S. Dort Highway	111.6	112	84	52	40	33
DBP3 North Flint Auto 3302 S. Dort Highway	96.5	127.2	88	48	31	28
DBP4 University Market 3606 Corunna	106.4	181.3	117	55	24	26
DBP5 B&P Gas Station 2501 Flushing	75.1	196.2	117	38	17	18
DBP6 Salem Housing 3216 MLK Boulevard	82.2	112.4	77	41	25	23
DBP7 Kroger 5018 Clio Road	88.2	144.4	94	49	30	27
DBP8 Taco Bell 6204 N. Saginaw	79.2	118.3	79	50	37	31

Briefly Message to Gov

Current sitx

Process

History

↓

Summ. w. 3 points

1. Zoning site Dw
2. Procedure w. Plat - DEL
3. Engage locals

As shown in the table above, even with this less restrictive modified method, six of the City's eight sites already exceed the OEL limit of 80 ppb for TTHM. In addition, the City's two other sites are both more than 95% of the TTHM OEL limit.

The MCL for TTHM and HAA5 is based on a locational running annual average for each site, essentially the average at each site over the four previous quarterly monitoring periods. However, with TTHM levels of this magnitude, it is likely the MCL will be exceeded for at least one of these eight sites from just three quarters of monitoring results. For TTHM, four quarters at the MCL of 80 ppb (4 x 80) would provide 320 ppb allowable. As an example, site DBP1 through just two quarterly monitoring periods has a total of 307 ppb (162+145), leaving only 13 ppb over two more quarterly monitoring periods to maintain compliance with the MCL.

Therefore, this office is requesting the City of Flint complete an Operational Evaluation in accordance with Administrative Rule 719l (R325.10179l). The Operational Evaluation Report shall be submitted to this office no later than November 28, 2014. The report shall not be limited in scope and shall include the following:

Examination of Treatment Operational Practices
- Changes in source water quality
- Treatment changes
- Storage tank operations
- Excess storage capacity
- Treatment problems that contribute to TTHM formation

Examination of Distribution Operational Practices
- Storage tank operations
- Excess storage capacity
- Distribution system flushing

The report shall also include steps the City could consider to minimize future exceedances.

Additional guidance on completing the Operational Evaluation Report, including a number of forms that can be used to gather and evaluate water system information is provided in the United States Environmental Protection Agency's (U.S. EPA) Operational Evaluation Guidance Manual. This document is available on the U.S. EPA's website at the following link:

http://www.epa.gov/ogwdw/disinfection/stage2/pdfs/draft_guide_stage2_operationalevaluation.pdf

Be advised, failure to submit an Operational Evaluation Report by this deadline is a reporting violation subject to Tier 3 Public Notification.

The OEL is an indicator of operational performance. The water system must take proactive steps to be able to comply with the MCL's for TTHM and HAA5. While it is recognized that removal of Total Organic Carbon disinfection byproduct precursors as part of the treatment process has performed above minimum removal requirements under the treatment technique, around 4 parts per million of organic carbon are still present in the treated water and may be leading to additional TTHM formation in the City's distribution system.

While health effects associated with disinfection byproducts contaminants are based on chronic exposure, the City has available alternatives that must be considered to achieve compliance with this drinking water public health standard.

Subject: DWSD response on sunk costs and non-contracted rates
Attachments: SKMBT_65213051611350.pdf

Liane,

Attached is the letter from DWSD (Sue McCormick) to Treasurer Dillon regarding stranded or sunk costs and non-contracted water rates to the City of Flint and Genesee County water systems. These were requested by the Governor during the meeting I attended on April 20, though DWSD was supposed to provide actual figures by the April 24 response.

While the DEQ does not involve itself in rate negotiations between parties, continued delays in not having these costs and rates negotiated creates burdens on both sides which places the ability to complete other capital improvement and rehabilitation projects in limbo, creating the potential for compliance issues. Uncertainties regarding the future of the DWSD also add complexity to this situation.

As both the City of Flint and City of Detroit will continue to reside under auspices of emergency financial managers administered by the Treasury Department for the near future, it is hoped that resolutions to these issues can be reached in a timely manner.

We would greatly appreciate it if you and/or Director Wyant could relay these concerns as part of the DEQ's continued discussions with the Treasury Department and keep things moving forward. We of course, will continue to provide any technical assistance they might request.

CITY OF DETROIT
WATER AND SEWERAGE DEPARTMENT
OFFICE OF THE DIRECTOR

735 RANDOLPH STREET
DETROIT, MICHIGAN 48226
WWW.DETROITMI.GOV

April 24, 2013

Mr. Andy Dillon, Treasurer
Michigan Department of Treasury
Lansing, Michigan 48922

Dear Mr. Dillon:

Regarding: Rate Proposal for Flint / Genesee County

As you are aware, during our meeting on Friday, April 20, 2013, the Detroit Water and Sewerage Department (DWSD) was requested to provide a rate proposal to Flint and Genesee County by today based upon the specifications that Flint provided to DWSD on Monday, April 22, 2013. Early this morning, DWSD responded to that request with several documents that were also provided to your office by electronic communication.

In addition to the proposal document, the State of Michigan requested that DWSD include cost figures concerning DWSD's stranded costs associated with capital investment made by DWSD over the years related to serving both Flint and Genesee County as water customers. This issue of "stranded costs" has received significant media attention over the past several months, and my impression is that the State was looking for a clear figure so that there could be subsequent discussion and negotiation over all costs associated with Flint's decision on whether to join Karegondi Water Authority (KWA).

As you may know, State law requires that public utilities such as DWSD must base their rates upon the actual cost of service to particular customers. Additionally, state law limits the length of utility contracts to thirty years, while the useful life of capital assets in the water utility can greatly exceed that thirty year term.

Unfortunately, the computation of stranded costs for DWSD's capital investments in capacity and transmission attributable to Flint's and Genesee's consumption of DWSD water, is a complex calculation that cannot be performed with any level of certainty over the short time period provided by the State of Michigan for this analysis. Further, I have been advised by DWSD's General Counsel that it would not be prudent to engage in a process of trying to guestimate a price range for such a complex computation.

Based upon DWSD's termination of Flint's existing water contract last week, DWSD has roughly twelve months to determine the appropriate cost structure for Flint and Genesee's water consumption over the remaining term of their non-contracted water service from DWSD. DWSD will, however, endeavor to finalize the rate impact of the stranded costs by the end of the current calendar year.

Please rest assure that DWSD's computation will be in accordance with State Law which dictates that such rates will not result in a rate structure that would generate a profit for DWSD. Our intent is simply to compute the rates so that costs properly attributable to Flint and Genesee County will not be borne by the remaining DWSD water customers.

Sincerely,

Sue McCormick
Director

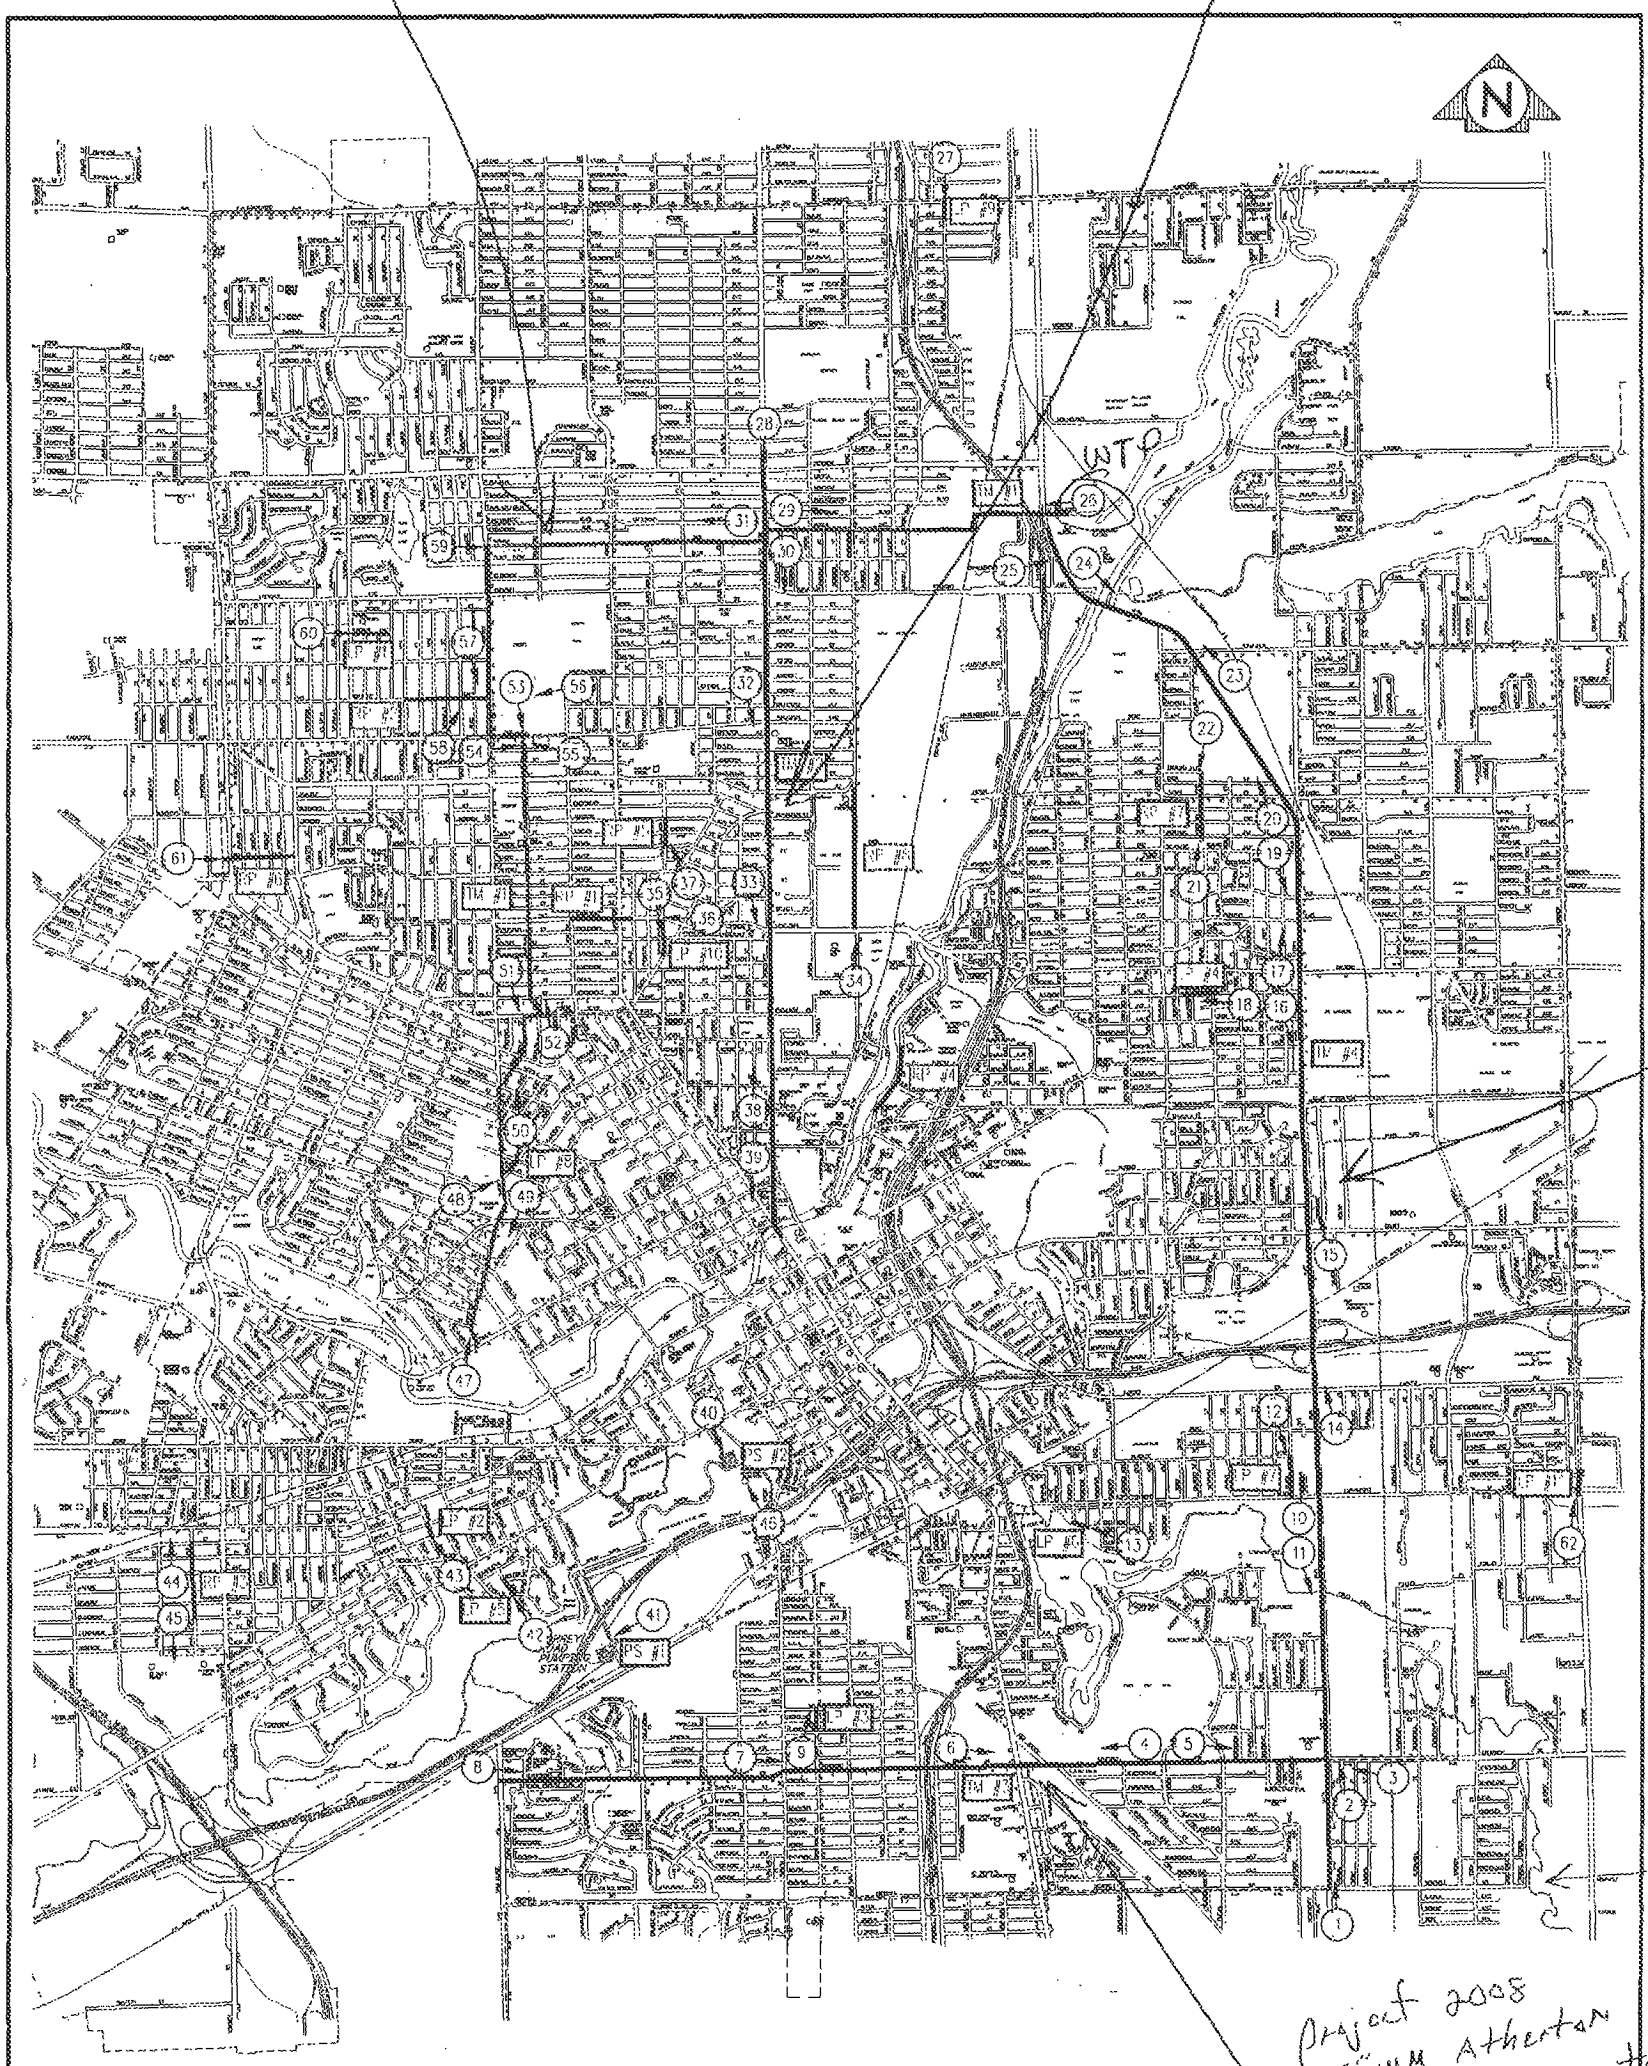
Subject: Genesee County Drain Commission - KWA

On December 13th, I received a phone call from John O'Malia, who will be coordinating the efforts between Wade Trim and AE COM for the Genesee County Drain Commission (a.k.a. KWA). The latter firm will be charged with developing the design criteria for the entire project and the preliminary transmission line route selection and the easement surveys. Wade Trim is involved with the intake construction project. The initial design criteria should be available in January or February of 2013. The present intent is to break the project down into several pieces for the actual design, such as having separate design projects for the low lift pump station, transmission line, reservoir, SCADA system(s) and treatment plant. The request for bids for the design work for each portion of the project may be advertised next month. There may be several consulting firms participating in the overall design. Genesee County will request to meet with ODWMA staff to discuss the design criteria early next year.

The city of Flint has provisionally accepted the offer to join the KWA. The city's approval is subject to the subsequent approval by the Department of Treasury. The state's approval (or possible hearings leading to the approval) is expected in January. There may be some opposition by DWSD about Flint participating in the project.



Genesee County has approved the sale of $30 Million of bonds. The county is expecting to obtain a 3% APR for the bonds.

Ben,

The Flint WTP is available all day...but gave them a heads up that it would most likely be in the early afternoon...I will pass this invite on to our other RMD staff....I expect that drinking water staff will be most interested in the visit.

Subject: Director's visit to Flint

We should go ahead and plan on a trip to the water treatment plant and the power plant for the 29th. So we need to determine what staff will be going, what times for the visits and the locations to meet the director. All of which we need to put together an give to the director who will be driving separately to an earlier meeting. We should meet this week once we know who is going and a street address for each visit.

1. INTRODUCTION

Tucker, Young, Jackson, Tull, Inc. (TYJT), at the request of the State Treasurer performed an analysis of the water supply options being considered by the City of Flint. The City of Flint is presently supplied potable water from the Detroit Water and Sewerage Department (DWSD). This supply is from a single 72-inch water main that terminates at a master meter located at Potter and Baxter. Additionally, downstream of the DWSD master meter, Flint supplies its customer Genesee County. The City of Flint also operates a water treatment plant that uses the Flint River as its source of supply to provide back up and redundancy to the DWSD supply as required by MDEQ

The Karegnondi Water Authority (KWA) is planning on constructing a raw water supply system that could provide Lake Huron water to the Flint Water Treatment Plant. Flint's existing plant would be upgraded to treat the new raw water source.

The State Treasurer has appointed an emergency financial manager for the City of Flint. As such the Treasurer has requested TYJT to provide an analysis of the water supply options to assist the Treasurer in determining any potential risk and the best course going forward for supplying potable water to the City of Flint.

Report Organization

The following sections of this report are described below:

Section 2 – The basis of the analysis is described in this section. The options include the KWA option and several options offered by DWSD.

Section 3 – A significant amount of information and data was collected including memorandums, reports, drawings, financial reports, and other documents. This section summarizes the information used in the analysis.

Section 4 – This section describes the evaluation of the cost of supply for the Flint options. The costs are comprised of the initial cost of operations plus the annual rate of escalation/inflation.

Section 5 – The evaluation process used to analyze the construction costs associated with the KWA supply system is described in this section. Additionally, the cost of financing the capital requirements is described.

Section 6 – This section presents the financial review of the options considered to supply potable water to Flint. A summary of these options is also provided.

Section 7 – In addition to the financial analysis other considerations were identified that should be considered in understanding the risks and determining the best option to supply Flint. They include items related to cost, redundancy and reliability, and Flint's ability to control their future cost of water supply.

2. FLINT WATER SUPPLY OPTIONS

Two water purveyor options were evaluated; the KWA water supply system and continued supply from DWSD. Both suppliers would provide water from Lake Huron as the source. The KWA system is a raw water supply, which means that the water would have to be treated by Flint before distributing the potable water to its customers. The DWSD supply is potable or "finished" water and would not need additional treatment.

Additionally, an option for the Flint WTP to supply the City of Flint without being supplied from either DWSD or KWA was initially considered. The preliminary investigation evaluated the cost associated with the required improvements to the plant and to the Flint River dam system. Although it appeared that this was a viable option, Flint in a meeting on December 20, 2012 with the Treasury, stated that the City did not want to pursue the option and it is no longer being considered.

Karegnondi Water Authority (KWA) Lake Huron Water Supply

The KWA water supply system schematic is shown in Figure 2-1. The system is comprised of an intake in Lake Huron that supplies water to the Lake Huron Pump Station (LHPS). The LHPS lifts the water and pumps it through an approximately 22 mile long 60-inch pipeline. The pipeline terminates at a 5 MG reservoir and is then pumped from the Intermediate Pump Station (IPS) through approximately 26 miles of 60-inch and 18 miles of 30-inch pipeline to the existing Flint WTP. Downstream of the IPS, approximately half way to the Flint WTP, the 60-inch line would also supply a new Genesee County WTP.

The raw water transmission system has a 60 MGD capacity and is sized to deliver a maximum of 18 MGD to the Flint WTP with an average day supply of 12 MGD. Improvements at the Flint WTP would also be required to treat the lake water as the plant is currently designed to treat the Flint River water.

The term of the KWA contract for Flint is 40 years.

Sized @ 18 MGD OR Contract MAY 8 ?
w. Rem to charge contract in Future if needed

KWA App. 20 says 36" main to Flint WTP

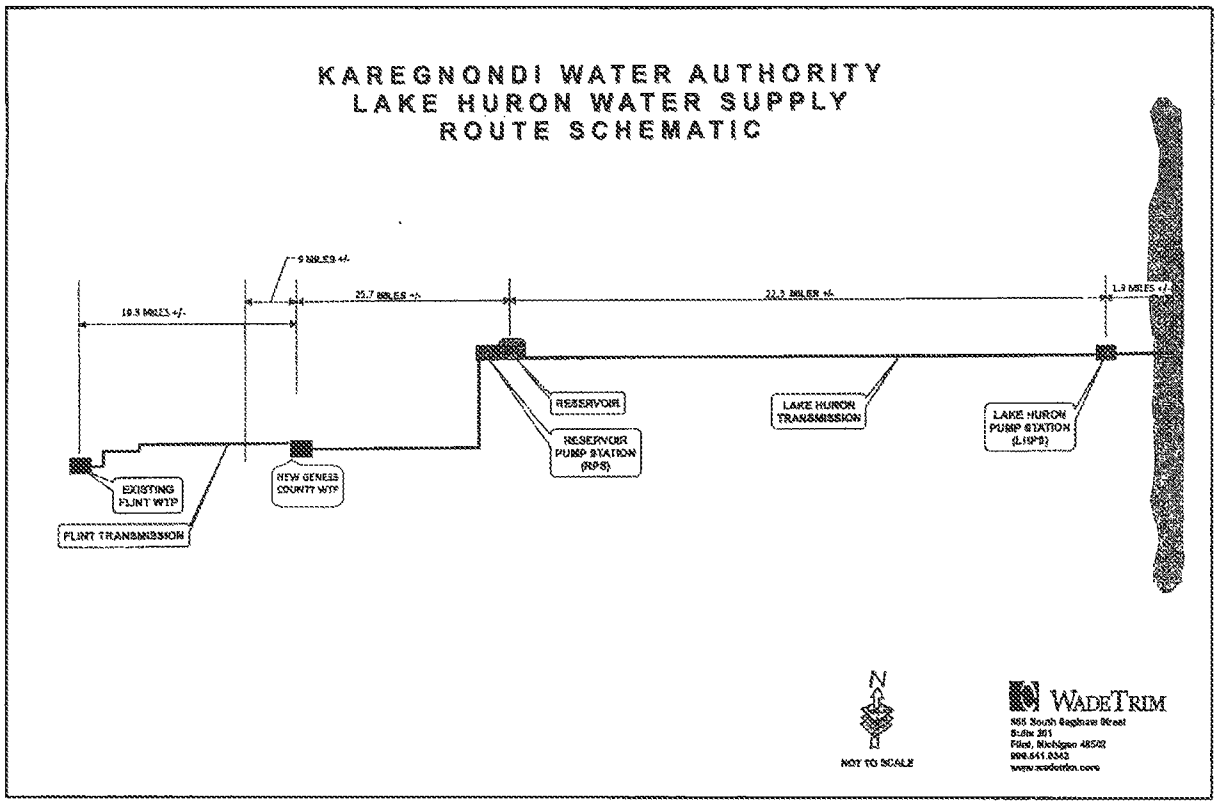

Figure 2-1: KWA Raw Water System

DWSD Water System

The DWSD system schematic is shown in Figure 2-2. Flint is currently supplied by DWSD at Master Meter FL-1, located at Potter and Baxter. Flint typically gets its water from the Lake Huron WTP, located in Fort Gratiot, Michigan; near the Lake Huron shoreline. Water is treated and pumped at the Lake Huron WTP and supplied through a 120-inch pipeline to an intermediate pump station called the Imlay Pump Station. The Imlay Pump Station has 20 MG of reservoir capacity. Depending on the time of year and the DWSD system demand, water is either bypassed directly to Flint or it is re-pumped at Imlay. It should be noted that the DWSD supply to Flint is part of a very large water system and during emergencies or outages water can be supplied from the south up to Flint in lieu of the Lake Huron facility.

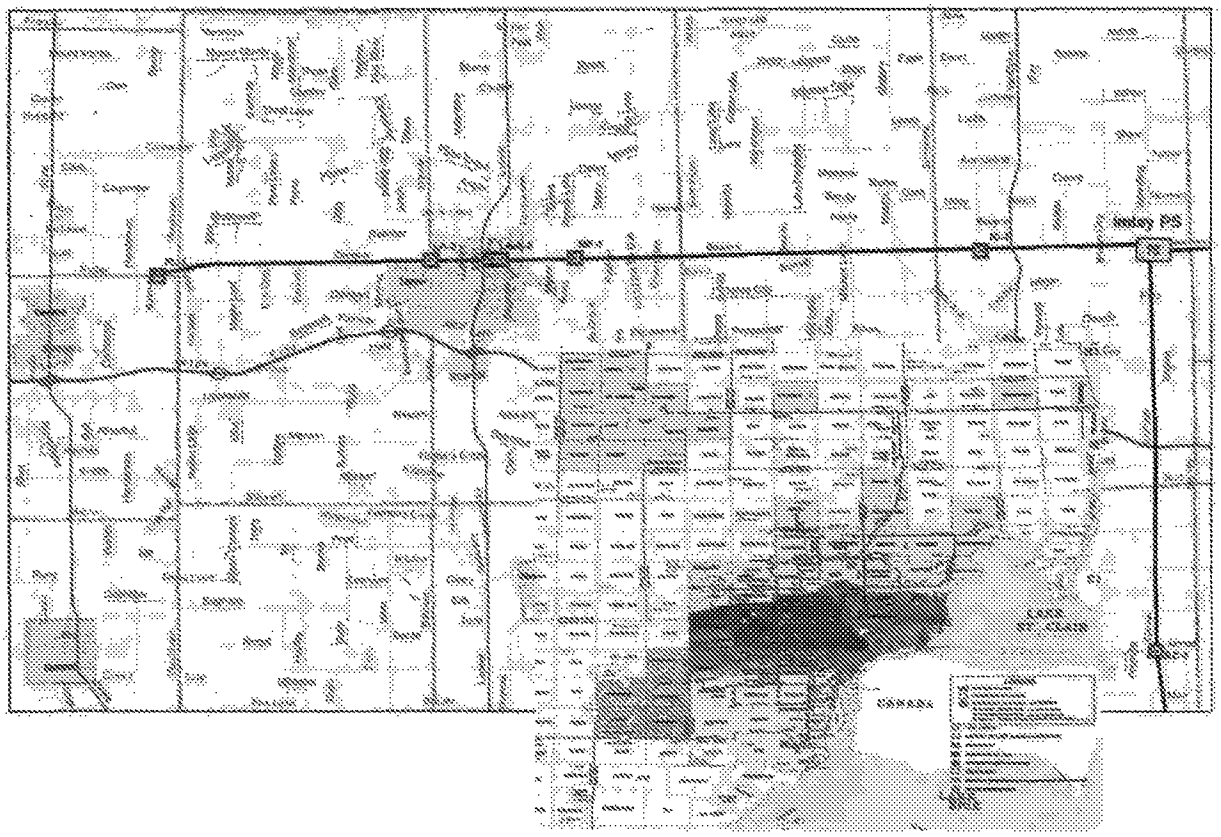

Figure 2-2: DWSD Water System

The pipeline from Imlay to FL-1 is a 72-inch pipeline. It has been estimated that the 72-inch line serving Flint has a capacity in excess of 90 MGD.

DWSD has presented several contractual options to Flint and all of them are based on Flint signing a new 30 year contract. The options shown in Table 2-1 are based on two different supply points; one at the current master meter location FL-1 at Potter and Baxter (P&B) and the other at the location of the Imlay Pump Station. The reason for the varying options is to provide a lower water rate at the Imlay Station, since the DWSD rate formula is based on distance and elevation factors related to the supply location.

The rates are also dependent on the maximum amount of water DWSD supplies. As example, if DWSD supplies a maximum day demand of 18 MGD that would equal the entire amount of water required by Flint.

For the options less than the maximum of 18 MGD means that the Flint WTP would supplement the difference by supplying water treated from the Flint River. These options are known as "blending" and would allow for Flint to blend two sources of water to supply its customers; the Flint River using the Flint WTP and Lake Huron from DWSD system.

18 MGD Maximum Day Customer – FL-1	12 MGD
12 MGD Maximum Day Customer – FL-1	8 MGD
8 MGD Maximum Day Customer – FL-1	8 MGD
12 MGD Maximum Day Customer - Imlay	12 MGD
8 MGD Maximum Day Customer - Imlay	12 MGD

3. DATA COLLECTION

During the course of the investigation several documents were used to perform the analysis. The names of the documents are listed below for reference.

KWA and Flint

- Preliminary Engineering Report, Lake Huron Water Supply Karegnondi Water Authority, September 2009;
- Analysis of the Flint River as a Permanent Water Supply for the City of Flint, July 2011;
- Cost Comparison, KWA vs. DWSD, Letter to Mr. Kurtz, October 31, 2012;
- Lake Huron Supply Study, KWA, Appendix 20, October 2012 Preliminary Report Update, Final Report (DRAFT), October 4, 2012;
- Articles of Incorporation of Karegnondi Water Authority, endorsed in 2010;
- Karegnondi Water Authority Bylaws, October 26, 2010;
- KWA Raw Water Supply Contract;
- Flint WTP Statement of Revenues and Expenditures 09' – 12';
- GCDC Division of Water and Waste Services Financial Statements 03' – 11'; and
- Assorted emails with further clarification of questions and documentation.

DWSD

- Historical Rates and Charges to Flint 04' – 13';
- Historical Rates and Charges to Flint with Hypothetical Model Contract 10' – 13';
- 2013 Rates and Charges for the following options:
  - 18 MGD Maximum Day Customer at FL-1;
  - 12 MGD Maximum Day Customer at FL-1 (Flint blending*);
  - 8 MGD Maximum Day Customer at FL-1 (Flint blending*);
  - 12 MGD Maximum Day Customer at Imlay (Flint blending*);
  - 8 MGD Maximum Day Customer at Imlay (Flint blending*); and
- Assorted emails with further clarification of questions and documentation.

* Flint blending based on DWSD supplying two-thirds and Flint one-third of 12 MGD average day demand.

Two meetings were also held; one with DWSD and one with Flint and Genesee County representing KWA. The meetings were held on November 19, 2012 and November 20, 2012, respectively. Minutes from these meetings are included in Appendix A.

4. COST OF SERVICE

Information provided by DWSD, Flint, and representatives of the KWA were used in the cost of service evaluation. To evaluate the annual escalation/inflation rate over the planning period, the rate adjustment for DWSD was estimated based on the recent rate adjustment history. For the KWA system both the estimated cost of operations when the system begins supplying water and the annual rate adjustment or inflation was evaluated. The existing cost of operations and escalation for the Flint WTP was based on actual costs provided and then adjusted depending on the scenario considered. This section describes the evaluation process and the rates used in the analysis.

DWSD Water Supply

The City of Flint has been a customer of DWSD since 1967. The Flint WTP has been maintained as a backup to the DWSD system. As indicated previously, several options were provided by DWSD depending on the type of service Flint was to select. The unit cost of water for each of these options is shown in Table 4-1. These rates are based on DWSD's FY13, which are current until July 2013.

18 MGD Maximum Day Customer – FL-1	12	16.37
12 MGD Maximum Day Customer – FL-1	8	16.31
8 MGD Maximum Day Customer – FL-1	8	12.68
12 MGD Maximum Day Customer - Imlay	12	14.38
8 MGD Maximum Day Customer - Imlay	12	11.11

Table 4-1: Cost of DWSD Supply Options

To determine annual escalation rate, DWSD's last 10 years of history was used along with other large urban water systems in Michigan. The water systems used for benchmarking comparison were: Lansing, Grand Rapids, and Saginaw.

Table 4-2 identifies the annual and average rate of increase to Flint based on supplying water either to the current FL-1 at Potter and Baxter or Imlay. Note the last three years of the rates (FY 2011 through FY 2013) assumes that Flint's cost would be based on the new 30 year contract; FY 2011 being the first year that the new contract was available.

Table 4-2: Recent DWSD Water Rates

Audited financial reports were used to determine the rate of inflation associated with other three large municipal systems. The results are shown in Table 4-3.

Lansing	05'-12'	4.6
Grand Rapids	04'-11'	1.6
Saginaw	04'-11'	7.0

Table 4-3: O&M Inflation Rates of Other Large Water Systems

Based on the information analyzed from DWSD and the other communities, it was determined that a fair annual rate of inflation for operations and maintenance cost for the analysis should be 4.4%. The 4.4% has historical significance from Flint's current water supplier and falls within the range of the other communities.

KWA Water Supply

The initial projected O&M cost for the KWA supply would be comprised of KWA's O&M costs as well as Flint's O&M costs. Because there was limited information provided, the initial estimated rate of $1.50/MCF was used. This rate is based on information from the cost comparison analysis attached to the letter to Mr. Kurtz, dated October 31, 2012.

The KWA cost evaluation used an annual O&M inflation rate of 5%. To validate this rate a similar analysis to DWSD's operations and maintenance annual rate of inflation was used. First, in discussions with Flint and the Genesee County Drain Commission (GCDC), they believed that the annual rate of inflation for the new KWA system would be similar to the GCDC Water & Waste Services (WWS). Additionally, two large transmission systems were used to benchmark the inflation rates: the Southeastern Oakland County Water Authority (SOCWA) and the Ypsilanti Utility Community Authority (YUCA). Although both of these systems transmit finished water opposed to raw water, they were considered similar enough for comparison as they are comprised of only large water mains, pumping facilities and storage.

Once again audited financial statements were used to calculate the inflation rates. A summary of the findings are shown in Table 4-4. Based on the fact that the information analyzed showed a large difference between the two systems, it was determined that the KWA assumption of 5% was a good rate of inflation to use in the financial analysis. This rate is almost equally between the GCDC rate and the other two transmission systems.

[illegible]	[illegible]	[illegible]
GCDC WWS	03' – 11'	10.5
SOCWA	04'-12'	–
YUCA	04'-12'	0.7

Table 4-4: O&M Inflation Rates of Other Comparable Systems to KWA

Flint WTP

The Flint WTP currently serves as a backup supply to the DWSD service to Flint. To maintain backup operations, the City of Flint operates the plant approximately 20 days each year. Flint indicated that the average production rate when they operate is 11 MGD.

For the blending options and the KWA supply considered, Flint would be required to operate its plant all year around. Therefore, their operating and maintenance costs were evaluated and adjusted to determine an annual cost associated with year-round operations.

The Flint WTP provided three years of operating costs for the assessment. Additionally, reports listed in Section 3 were also used as reference to determine both operating costs for the plant processing Flint River water (blending options) and Lake Huron raw water (KWA option).

Major cost centers were analyzed to estimate annual operation and maintenance. They included: labor, utilities, chemicals and residual management. In general, as recommended by the Flint plant staff, labor and overhead were increased from the current costs by two-thirds. Additionally, variable costs for power, chemicals and residual cost were increased to estimate full time treatment at the Flint WTP. Data from the KWA Preliminary Report and annual operating data for the Flint WTP (provided separately) were analyzed to make these forecasts.

The annual operating and maintenance costs developed for Flint WTP used are shown in Table 4-5.

[illegible]	[illegible]	[illegible]
Flint River (Blending with DWSD)	4	$5,895,097
Lake Huron (Supplied by KWA)	12	$7,913,118

Table 4-5: FY 13 O&M Costs for Year-round Operations

It was determined that a fair annual rate of inflation for operations and maintenance cost for the Flint WTP plant should be 4.51%. The 4.51% is an average of Lansing, Grand Rapids and Saginaw facilities.

Flint ADD For May Month ?

5. CAPITAL REQUIREMENTS

Large capital investments would be required by Flint and GCDC to construct the KWA supply system. Furthermore, some of the options presented by DWSD (supply point from Imlay) would require the purchase by Flint of DWSD's 72-inch water main. Performing the financial analysis; therefore, required an analysis of the KWA construction cost estimate for the transmission system and Flint WTP improvements.

Revenue bonds were also identified as the source of financing the new supply system and associated improvements. This section describes the assumptions made and the interest used for financing the improvements.

KWA Supply System

The most current cost estimate of the KWA system was presented in the document titled; Lake Huron Supply Study, KWA, Appendix 20, October 2012 Preliminary Report Update, Final Report (DRAFT), October 4, 2012. The cost of construction is estimated at $272,421,558. Flint's portion would be 30% or $81,726,467.

Due to the significance of this expenditure, a detailed review of the cost was performed and is presented in this section. The analysis was performed based on the main elements of the supply system: the lake intake, the two pumping stations, and the transmission pipeline. Additionally, an analysis was performed related to construction contingencies and other costs such as engineering, legal, and administration.

Lake Intake

KWA representatives indicated in a meeting in November that the design documents for the intake were at 90% and that it was planned for advertisement in January 2013. A summary of the estimate is shown in Table 5-1.

[illegible]	[illegible]
Intake and Crib	$22,076,850
ELAC at 25%	5,519,213
Property	2,300,000
Total	**$29,896,063**

$ 24.6 B.D

Table 5-1: KWA Intake Cost Estimate

Based on the evaluation, it appeared that the cost estimate was reasonable. Given that the design was nearly complete, the engineering, legal, administration, and construction contingencies (ELAC) at 25% were also found to be appropriate.

Pumping Stations

KWA representatives indicated that the pump stations were estimated at a level of design less than 15%. Therefore, in addition to an evaluation of their cost estimate, other water pumping station costs were used for comparison. Additionally, contractors were also contacted for costs. Table 5-2 summarizes the KWA cost estimate compared to our cost estimate performed for the Treasury.

	KWA Estimate		Treasury Estimate
Pumping Stations	$24,618,080		$54,573,314
Land for Intermediate Pump Station and Reservoir	--		75,000
Subtotal	$24,618,080		$54,648,314
ELAC for Construction	25% 6,154,520	30%	16,394,494
Total	$30,772,600		$71,042,808

Table 5-2: Pumping Stations Cost Estimate

Two things to note regarding the difference in the cost estimates; firstly, there is a large difference in the cost estimates of the pumping stations. The estimate developed for the Treasury used several other pumping stations construction costs from Southeastern Michigan and discussions with contractors. These costs were then computed on a $/MG's for comparison.

Secondly, our estimate for the Treasury is based on an ELAC of 30% instead of KWA's 25%. Although 25% was acceptable for the intake, it is believed to be too low for the pumping station estimate given that the engineering effort is less than 15%.

Transmission Main

Although the specific route for the transmission main was not provided, an estimate was calculated based on the general information provided. Once again, the KWA estimate was based on a level of design less than 15%. The estimate performed for the Treasury used the line items provided by KWA for the pipeline and also consulted with contractors to evaluate the cost of construction. The comparison is shown in Table 5-3.

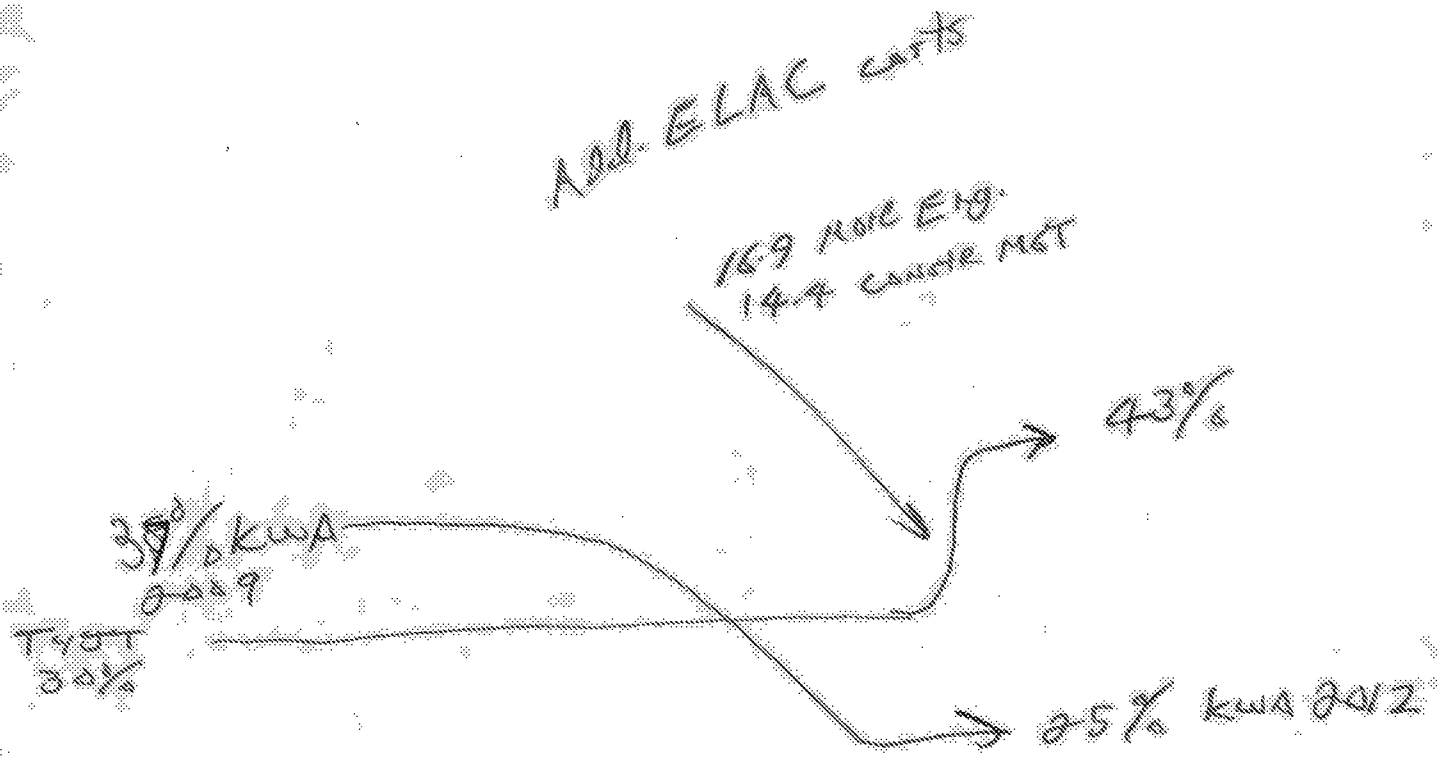
Although the cost of construction of the pipeline is similar, a value of 30% was used for ELAC due to the level of design. Additionally, KWA did not believe there would be any additional costs for easements; however, this did not seem practical. Therefore an estimate for acquiring the easements was added to the Treasury estimate and is based on the 277 easements identified by KWA. The cost shown includes surveying, legal, engineering, administration, etc.

Transmission Mains		$166,202,316		$167,419,530
ELAC for Construction	25%	41,550,579	30%	50,225,859
Subtotal		$207,752,895		$217,645,389
Easements		-		1,166,170
Total		**$207,752,895**		**$218,811,559**

Table 5-3: Transmission Pipeline Cost Estimate

Other KWA Costs

In prior estimates of the construction cost, KWA used an ELAC of 37%. In this case it could be considered that the engineering effort associated with the design would have been included. However, it is believed that KWA's reduced ELAC of 25%, does not include the design effort. Additionally, it would be prudent to assume that the owner would want a construction manager during construction of this large project. A summary of these costs are shown in Table 5-4.



Design Engineering for Pumping Stations and the Transmission Pipeline	$16,939,581
Construction Management at 5%of Project Cost Estimate of $217,645,389	14,434,609
Administration	349,440
Legal, Easements, Contract Documents	831,000
Total	**$32,554,630**

Table 5-4: Other Costs

Summary Comparison

A summary of the two cost estimates are shown in Table 5-5. Based on the comparison, the estimate performed by TYJT shows a higher cost to Flint by approximately $25,000,000.

Note that there are two other costs shown in the summary that were not previously addressed; power and backup power. Regarding the cost of providing power to the pumping facilities, the cost of $4,000,000 appears reasonable.

Add. ELAC units
KG-9 non Eng.
14-4 Cable net
43%
35% KVA
0.9
T150T
30%
35% KVA 0.12

The KWA has repeatedly indicated that backup power is not needed. Backup power is a standard practice in the water industry. Furthermore, a loss of power at either pumping facility will prevent the supply of water to both Flint and Genesee County. For these reasons, the cost of providing backup power was included in our estimate for the Treasury.

Description	KWA Estimate	DWSD Estimate
Intake/Crib	$ 27,596,063	$ 27,596,063
Pump Stations	30,772,600	71,042,808
Transmission Mains	207,752,895	217,645,389
Power	4,000,000	4,000,000
Redundant Power for PS		1,273,200
Land for Lake Huron Pumping Station	2,300,000	2,300,000
Design Engineering/PS and Transmission		16,939,581
Construction Management		14,434,410
Administration		349,440
Legal/Easement/Contract Documents		831,000
Easements		1,166,170
Total	**$ 272,421,558**	**$ 357,578,060**
Flint Share at 30%	**$81,726,467**	**$107,273,418**

Table 5-5: Total Cost Comparison

Flint WTP Improvements

The KWA analysis identified capital costs required to convert the existing WTP from river water treatment to treating lake water. The cost estimate was identified as $7,100,000 in the 2009 report. This number was used in the our analysis, since additional information was not provided. For the purpose of the financial analysis; however, the $7,100,000 was increased by 3% each year for three years to account for inflation.

DWSD Imlay Station Supply Options

The options identified by DWSD to supply service to Flint at the Imlay Pump Station would require Flint to purchase the 72-inch water main from Imlay to Master Meter, FL-1. The pipeline is approximately 25 miles long. The estimated cost provided by DWSD for estimating purposes is $4,700,000.

Financing

The cost of financing the revenue bonds for the capital work was investigated. Based on conversations with local financial advisors knowledgeable in bond financing, an interest rate of 5% for the 25 year

period was considered acceptable. This is based on a Standard and Poor's bond rating of A without insurance.

Additional costs associated with the bond include the reserve and bond issuance fee. The bond holders will require a reserve of approximately 10% of the loan to be held for the 25 year payment period. The cost associated with the bond issuance has been estimated at 2.25% of the principal borrowed for the KWA project and 3% for the smaller loan associated with the Flint WTP improvements or the purchase of the 72-inch main.

Furthermore, since no revenue will be generated to pay on the bonds for the first three years that the system is being constructed, the cost associated with capitalizing the interest was also included.

Finally, interest on the reserve will be provided back to KWA and Flint. Although the interest is currently less than 1%, it was determined that a 3% rate would be more prudent long-term.

DWSD options laid out

6. FINDINGS

Using the information described in the previous sections, a cost evaluation was conducted for the KWA supply and the DWSD options. Individual worksheets for each option are provided in Appendix B. For the purpose of comparison a 30 year period was used. This period includes the 3 year construction period, the 25 loan period and an additional two years to get a sense of the cost of operation after the loans have been paid.

There were three separate cost sheets prepared for the KWA option. The first cost sheet (KWA) is based on the cost estimate provided by KWA. The costs provided assumed no overruns or delay in construction. With KWA's own assumptions of an overrun in construction of 15% and a one year delay in operations, the KWA estimated cost becomes $686,375,920 through Year 2042.

Since this cost estimate did not appear to include the financing of revenue bonds, another cost sheet (KWA-1) was developed that included KWA's cost estimate without overruns with the additional finance costs associated with the revenue bonds. A final cost sheet (KWA-2) includes the cost associated with the revenue bonds based on the estimate provided by TYJT for the Treasury.

A summary of the cost sheets provided in Appendix B are shown in Table 6-1. Figure 6-1 shows the cumulative annual costs associated with each option.

8 MGD MAX day will force Flint to use >10 MGD Put KWA WQ issues soften Sludge disp. Buried - enc

	Total Cost through 2042	Option #
DWSD 8 MGD Maximum Day at Imlay Station	634,795,488	1
KWA *(10/31/12 No Overruns, As Provided)**	649,775,166	2
DWSD 8 MGD Maximum Day at FL-1	672,671,705	3
KWA-1 *(10/31/12 No Overruns with Cost of Financing)*	707,279,715	4
DWSD 12 MGD Maximum Day at Imlay Station	725,576,803	5
DWSD 12 MGD Maximum Day at FL-1	762,110,308	6
KWA-2 *(Treasury Estimate)*	766,784,313	7
DWSD 18 MGD Maximum Day at FL-1	821,226,268	8

$ 172 M ll

* $686,375,920 with 15% overrun in construction and a one year delay in operations

Table 6-1: Total Cost of Options through 2042

Based on the analysis, it is prudent to assume the KWA water supply option costs would be somewhere between the KWA-1 and KWA-2 options. Therefore, the analysis indicates that the two DWSD options of supplying 8 MGD on a maximum day and up to 8 MGD on average are the least cost options for Flint. These options allow Flint to maximize the use of existing assets; the City of Flint's (the Flint WTP) and DWSD's (the existing 72-inch main).

Additionally, in recent conversations with the Treasury another option was discussed that could potentially be the most cost-effective solution. Currently the Flint WTP serves as a backup if service is

lost through either the DWSD or KWA pipeline. If the a twin pipe paralleling the DWSD 72-inch water main were constructed with interconnects with the 72-inch line, then the new water main could serve as the backup to Flint and the Flint WTP could be abandoned or potentially sold to Genesee County for their use.

The construction of the parallel pipeline would be considered in the DWSD capital expenditure as a Common to All (CTA) cost. This means that the capital cost of the pipeline would be shared by all DWSD customers and not just by Flint. Preliminary analysis of this option appears to be the most cost-effective of all the options discussed. However, a more thorough cost analysis is warranted and this approach would require an agreement between Flint and DWSD.

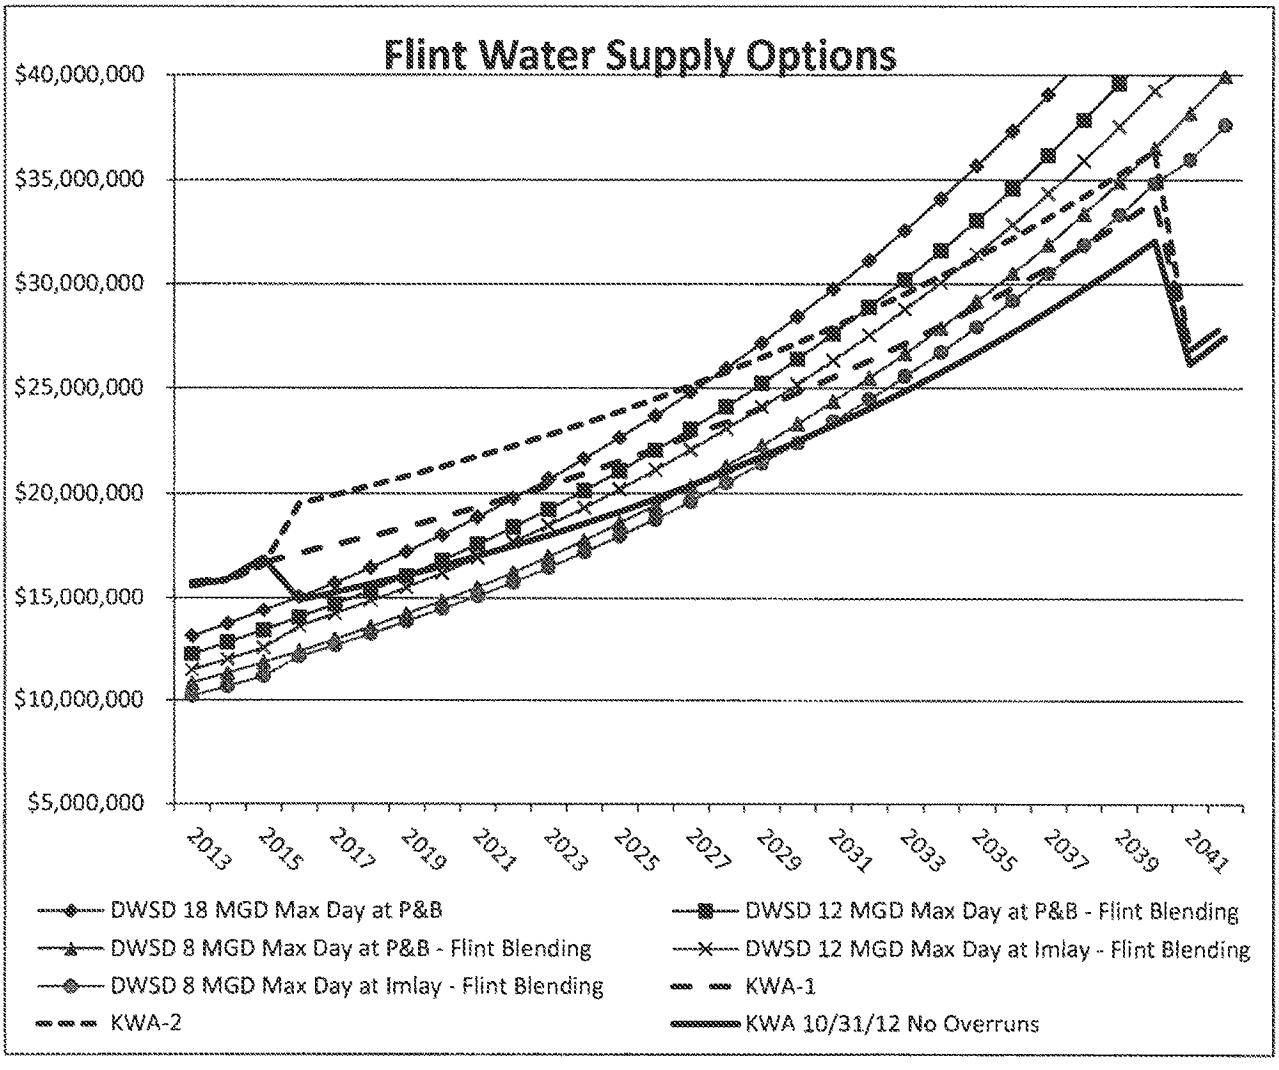


Figure 6-1: Flint Water Supply Options through 2042

7. OTHER CONSIDERATIONS

As part of the investigation other issues were identified that may result in risks to Flint that should be considered by the Treasury in determining how Flint's potable water should be supplied. These issues are related to redundancy and reliability, other items affecting cost, and Flint's desire to control its own destiny related to its water supply. These are described further below.

Redundancy/Reliability

In one of the first meetings related to this task assessment, which was held on November 1, 2012, the Genesee County Drain Commissioner, Mr. Jeff Wright, stated that one of the main reasons for pursuing the KWA supply option related to the lack of reliability of the DWSD system. He pointed to the Northeast blackout of 2003; a widespread power outage that occurred throughout parts of the Northeastern and Midwestern United States and Ontario, Canada, on Thursday, August 14, 2003. He stated that Flint and Genesee County were out of water for several days.

It is worth noting that this was a power outage of historic proportions that affected millions of Americans. However, DWSD did begin supplying water again relatively quickly in comparison to other major cities impacted by the same power outage.

Furthermore, the KWA supply system offers less redundancy to Flint than the current DWSD system. Under both options, Flint is supplied by a single pipeline; however, DWSD has backup power at all of its major facilities supplying Flint. The KWA system will not have a redundant power at its pumping facilities. This would be a major risk.

Currently, backup to the DWSD system for Flint is Flint's WTP using the Flint River as the source of supply. KWA has stated that the Flint River source would also be used as backup to Flint if the KWA supply through its pipeline was lost. However, since the Flint WTP would be upgraded to treat Lake Huron water under the KWA option, using the Flint River as a backup source would require the Flint WTP to maintain two process treatment streams.

In addition to Flint and Genesee County, the DWSD's 72-inch main supplies Imlay City, Mayfield and the Greater Lapeer County Utilities Authority (GLCUA). The volume of water contained within the 72-inch main is approximately 30 MG. Only supplying these three remaining communities would cause the water age to increase dramatically; somewhere in excess of three weeks old, before reaching the customers' master meters. Since the half-life of chlorine in the DWSD system is approximately 5 days, the chlorine would most probably be near zero requiring re-chlorination of the finished water upstream of the master meters.

Re-chlorinating is a costly and risky process due to the instability of chlorine gas. It is unknown whether DWSD would pursue this improvement or possibly abandoned the 72-inch pipeline.

If Flint is supplied by the KWA system, then DWSD supplying their other customers along the 72-inch water main may be reconsidered. Since the KWA system is a raw water supply, the communities would

either have to build a treatment facility to treat the water from KWA or find another water source for their communities.

Additional Cost and Risk Considerations

The design of the KWA supply and the construction of the system have not been completed; therefore, final costs and time to complete are unknown. Cost overruns and delays in completion will both negatively impact Flint's final cost. As example, if the project is not completed within the three year period, payment on the bonds will be due, but the revenue source needed from the sale of water could not be provided.

Furthermore, there is always a risk with large water system construction; especially those including an intake in the Great Lakes, pumping stations and rehabilitation of older water treatment plants. These risks include the potential of explosive gases in tunneling below Lake Huron, changing site conditions associated with the large number of miles of pipe installation and rehabilitating an older WTP, and the startup and debugging of the entire pumping system.

Flint has indicated that they have a high water loss. Not addressing this issue prior to sizing the Flint supply pipeline from KWA could cause the water main to be oversized along with its incremental cost in construction.

Also, the KWA supply option appears to run counter to the Treasury's Competitive Grant Assistance Program (Formerly EVIP Grant). This program has been put in place to allow for communities to consolidate their services and save money. Two existing customers of DWSD (Flint and Genesee County) along with the potential of others customers (GLCUA, Mayfield, Imlay City) separating to from another water system is in contradiction to the program.

Finally, there is a concern over the ability of smaller systems (KWA) over larger systems (DWSD) to pay for future unfunded mandates and regulations. Obviously, identifying regulation requirements over 30 years is hard to determine. However, it is widely accepted that a large system has greater ability to respond to unfunded mandates because the cost can be distributed over a large customer base.

Flint's Autonomy

Flint has indicated that a major point of consideration is that they have no control over the rate increases issued to Flint by DWSD. All other counties supplied by DWSD have representatives on the Board of Water Commissioners (BOWC). The BOWC is one of the governing bodies that approve the water rates. Since Flint and Genesee County do not have a representative on the BOWC, Flint believes they are held "hostage" to DWSD's rates and cost of service.

This issue was stated in Flint's handout at the November 1, 2012 meeting. The handout is titled, "Flint Water Supply Future." However, it is worth noting in the same handout, Flint also identifies similar concerns with the governing board of the KWA system. Notably, that although Flint and Genesee County will be the only customers and Flint will be responsible for 30 percent of the construction cost,

they will have a minority vote on the KWA board. Furthermore, there are other communities (Lapeer County, the City of Lapeer, and Sanilac County) that sit on the board and vote. However, they are not purchasing water nor contributing to the construction costs.

MEETING MINUTES

IN ATTENDANCE:	Sue McCormick, DWSD Director Darryl Latimer, DWSD Deputy Director George Karmo, TYJT Awni Qaqish, TYJT Dave Guastella, TYJT
DATE:	November 24, 2012
PURPOSE OF MEETING:	Meeting with DWSD for the Indefinite-scope, Indefinite-delivery Contract Number 00383, 2012 Professional General Architectural/Engineering Services – City of Flint Water Supply Assessment
PREPARED BY:	Dave Guastella

A meeting was held at the DWSD Main Office Building on November 19, 2012 to discuss the water supply options being presented by DWSD to the City of Flint. The main items discussed generally followed the attached DWSD Discussion/Questions that were provided to the Department prior to the meeting. A summary of the key points discussed are provided below.

DISCUSSION ITEMS

1. Question/Discussion Item: Verify that the four options presented at the November 1, 2012 meeting are still available for consideration:

    a. Supplied from Potter & Baxter using the new model contract (assume a Maximum Day Customer),

    b. Supplied from Imlay Station,

    c. Finished un-pumped supply from Lake Huron WTP, and

    d. Raw un-pumped supply from Lake Huron WTP.

    DWSD prefers to focus on the first two supply point listed; from the current location at Potter & Baxter and at the Imlay Pump Station as these apply specifically to Flint.

    DWSD provided the attached summary regarding the current costs to Flint based on the various options that DWSD is offering. The savings associated with each option is provided as well. As example, if Flint were to purchase water from the supply point located at Imlay Station, the current cost to Flint would be $5,661,000 and it would be a savings of nearly 50%

Comments: Meeting minutes were recorded based on the understanding of the author. Please contact the author within three days if you have any different understanding of the meeting. These minutes will be considered approved unless comments are provided within three days.

compared to Flint's current rate.

2. Question/Discussion Item: What additional capital improvements will be required for each option?

   If Imlay Pump Station is selected as the supply point then Flint would need to purchase the 72-inch water main and an agreement to supply Lapeer would need to be worked out. DWSD believes that this could be worked out through a "wheeling" charge over the 72-inch main or possibly moving the supply point downstream of the Lapeer connection.. DWSD estimates the value of the water main at $4.7M. Flint could bond for this amount or DWSD could include the cost into Flint's rate.

3. Question/Discussion Item: Are there other options being presented that should be considered (e.g., blending)?

   Only the two options indicated above are currently being considered and both would include blending; DWSD providing 2/3 of the supply and the Flint WTP providing the other 1/3.

4. Question/Discussion Item: To evaluate each option over the 25 year planning period, provide:

   a. Annual water rate for Flint for 2002 through 2012, and the

   b. Projected annual rate adjustment for each option. What are the proposed measures to keep the rate adjustments down in the future?

   DWSD provided the attached historical rates from 2002 through 2012 for the existing water contract with Flint. The attachment also includes what the rates would have been if Flint had signed the new model contract or had taken service from Imlay. These rates were provided back to 2010.

   DWSD believes that 5% would be a good estimation to assume for their annual escalation in rates over the 25 year planning period.

5. Question/Discussion Item: Flint stated a 10% increase in the capacity charge. What number did DWSD provide Flint?

   It was unclear to DWSD where the 10% increase in capacity charge stated by Flint came from. DWSD's information provided shows an average of 6.3%. DWSD offered a meeting with TYJT to discuss how the fixed and commodity charges are allocated.

6. Question/Discussion Item: Flint financial comparison is based on the initial Cost of $14,413,858, which includes $2,725,538 for Flint WTP operating cost; i.e, DWSD charge is $11,688,320. How good is this number?

   DWSD indicated that the charge of $11,638,320 is good through 6/30/13.based on their existing contract with DWSD.

7. Question/Discussion Item: KWA's initial charge to Flint is based on 12 MGD. Is DWSD charge

based on 12 MGD?

Yes, 12 MGD from DWSD would be a maximum with Flint supplying 6 MGD for a total of 18 MGD (2/3 vs. 1/3).

Comments: Meeting minutes were recorded based on the understanding of the author. Please contact the author within three days if you have any different understanding of the meeting. These minutes will be considered approved unless comments are provided within three days.

DATE: November 24, 2012

PURPOSE OF MEETING: Meeting with the City of Flint for the Indefinite-scope, Indefinite-delivery Contract Number 00383, 2012 Professional General Architectural/Engineering Services – City of Flint Water Supply Assessment

PREPARED BY: Dave Guastella

A meeting was held at the City of Flint Municipal Center on November 20, 2012 to discuss the water supply option being presented by the Karegnondi Water Authority (KWA) to the City of Flint. The main items discussed generally followed the attached KWA Discussion/Questions that were provided to City prior to the meeting. A summary of the key points discussed are provided below.

The questions submitted are repeated in the Discussion Items for easy reference. A summary of the action items generated from the meeting follow the Discussion Items.

DISCUSSION ITEMS

1. Question/Discussion Item: Is the maximum day demand of 18 MGD for Flint the maximum day demand (MDD) throughout the 25 year planning period? If not, what is the 25 year projected MDD?

   KWA would supply up to 18 MGD. 18 MGD has been assumed as the maximum day demand and 12 MGD is assumed as the average day demand throughout the 25 year planning period.

2. Question/Discussion Item: Copy of the intake contract documents and engineer's estimate.

   The intake contract documents are approximately 90% complete and are not available for distribution. However, the updated Appendix 20, dated October 4, 2012 includes the most recent cost estimate of the intake based on the current design in process.

Comments: Meeting minutes were recorded based on the understanding of the author. Please contact the author within three days if you have any different understanding of the meeting. These minutes will be considered approved unless comments are provided within three days.

3. Question/Discussion Item: Documentation of the Flint WTP improvements required and cost estimate.

   The costs are approximately $7M as presented in the September 2009 Preliminary Engineering Report. However, this estimate has been updated. Some processes have been eliminated. John O'Brien will provide the updated costs and the description of the planned improvements to the plant.

4. Question/Discussion Item: Confirm Flint's allocated percentage of the KWA capital improvements (30%?).

   Yes, the allocation is based on 18 MGD/60 MGD total capacity.

5. Question/Discussion Item: Copy of the proposed KWA operating agreement for Flint.

   John O'Brien will provide the operating agreement as well as the Capacity Contract and Articles of Incorporation.

6. Question/Discussion Item: What is the annual operating agreement adjustment projected for the 25 year planning period?

   This information is provided in Appendix 14, Table 14.2 of the September 2009 Preliminary Engineering Report. Operating cost based on Table 1. Used 12 MGD as average day demand (ADD). Assumed 5% as the annual increase in operating costs. John O'Brien indicated that these operating costs were based on Genesee County's operating costs. John O'Brien will provide the last 10 years of audited financial statements for the water fund.

   To assess operating and maintenance costs for the Flint WTP, Duffy will provide multiple years of financial statements for the water fund. Duffy did not believe they had 10 years, but they will provide what they have.

   Regarding operation and maintenance costs, Flint believes that these costs will increase by 2/3 of what they are now.

7. Question/Discussion Item: Need the route of the pipelines and the locations of the facilities proposed. Purpose is to identify constraints that impact costs (i.e., utilities, environmental (e.g. wetlands), easements, etc.).

   KWA will not release the route due to concerns regarding speculation of land and easements. John O'Brien did indicate that the Lake Huron pump station would be at Fisher and M-25. The intermediate pump station site is near a location of the Lapeer/Sanilac/St. Clair border; where all three meet.

8. Question/Discussion Item: KWA's initial charge to Flint is based on a 12 MGD average day demand. What is the basis of this number? Are there population projections and water use figures available that were used to determine the Flint demand for the 25 year planning period?

Comments: Meeting minutes were recorded based on the understanding of the author. Please contact the author within three days if you have any different understanding of the meeting. These minutes will be considered approved unless comments are provided within three days.

This was answered in Question No. 1 above.

9. Question/Discussion Item: Is there a transition plan and cost during construction of the KWA system identified?

   Flint is looking for an agreement with DWSD for back-up supply from the 72-inch main at the Genesee border.

10. Question/Discussion Item: The October 4, 2012 Preliminary Engineering Report Update states: "no backup power is planned for the pumps" (LHPS) and "No backup power is planned for pumping" (IPS). In case of power loss, how would Flint supply its customers?

    Flint indicated that they have adequate storage to supply the system for 6 to 7 days. Flint has 55 MG of storage and Genesee County has 65 MG for 2.5 days.

11. Question/Discussion Item: The latest plan shows only a 5 million gallon ground reservoir is planned for balancing between LHPS and IPS. How is redundancy maintained?

    In cases of emergency, Flint indicated that the back-up for the KWA system will be the same as it is now with DWSD; they will use the Flint River as the source water. Flint currently operates their plant four times a year.

    When questioned as to whether the WTP will be able to treat both lake water from the KWA system and river water Flint indicated that once the improvements identified in the September 2009 Preliminary Engineering Report are completed they will be able to accomplish both treatment processes. Flint will provide a schematic of the treatment trains at the WTP and a copy of the Flint transmission system.

    Genesee County indicated that additional redundancy would also be provided from the new Genesee County WTP.

    Regarding hydraulic transients; Genesee County indicated that a model analysis has not been included, but capital costs for mitigating transients have been included.

12. Question/Discussion Item: Related to the construction cost:

    a. Does it include an additional traffic lane since the construction will occupy half the right of way? *Not required, all roads are county roads; however, there are a few State road crossings.*

    b. Does it include costs/fees for permit requirements such as inspection cost by the jurisdictional authorities? As a point of reference, the permit fee costs for the Flint Transmission System came out to be $5.8 million. *Not required; all of the counties have waived any fees.*

    c. Does the cost of the steel pipe segments include corrosion protection measures such as

anode stations and related O&M? *Yes; however, the KWA has not settled on using steel pipe. PCCP pipe may be used. Steel shown in estimate because it is highest in cost and therefore the pricing is conservative.*

d. SCADA monitoring stations require power. Is the cost of bring power to the SCADA stations included? Again, as a point of reference for the Flint Transmission System we estimated $800,000 for power to SCADA and valve operators. *Yes, Genesee County did emphasize that the SCADA system will be simple and straightforward because a lot of controls are not required.*

e. Other items discussed at the meeting included:

- The 2009 plant improvement cost is still good; however, there will be some reduction, such as a sulfuric chloride feed system that was eliminated. Plant capacity now is 36MGD, but will be 18 MGD.
- The KWA Lake Huron Pumping Station (LHPS) is now only high lift pump station.
- Genesee County will provide the distance of the intake pipe from the crib to the LHPS.
- The intake project is almost ready to bid; waiting for the COE permit.
- Genesee County is estimating the construction for the pipe lines and pump stations will begin July 2013.
- The route has been flown for survey.
- Genesee County is estimating construction will be complete and the project will be placed in service by Jan 2016.
- Genesee County to provide a list of assumptions that the $272 million cost estimate is based on since the route is now known.

13. The Flint River is identified as a backup: At what capacity? MDD or emergency supply?

The Flint River would serve as a back up supply.

14. Where did the 40 years come from (Flint hostage to Detroit)? DWSD's new contracts are 30 years with openers to revise terms of supply (volume and pressure) after the first two years, then three years, and then in five year increments thereafter.

The 40 years was stated in error. The reference was to DWSD's requirement to sign a 30 year contract.

After 40 years Flint will own 30% of the project and can sell their share of ownership if they want. Conversely, with DWSD, they continue to pay for the capital projects but have no ownership. Flint believes they will know what they will be charged for the next 25 years versus DWSD that can't commit to a fixed escalation.

Comments: Meeting minutes were recorded based on the understanding of the author. Please contact the author within three days if you have any different understanding of the meeting. These minutes will be considered approved unless comments are provided within three days.

Action Items for Follow-up		
Items:	*Assigned To:*	*Date to Complete*
1. Updated Costs for the Flint WTP improvements and a description of the improvements.	John O'Brien	11/21/12
2. KWA Operating Agreement, Capacity Contract and Articles of Incorporation.	John O'Brien	11/20/12
3. Provide the last 10 years of audited financial statements for the Genesee water fund.	John O'Brien	11/20/12
4. Provide multiple years of financial statements for the City of Flint water fund.	Duffy Johnson	11/26/12
5. Provide schematic of the Flint WTP and a map of the Flint transmission system.	Brent Wright	11/26/12
6. Provide the length of the intake pipe from the crib to the pump station.	John O'Brien	11/20/12
7. Provide a list of assumptions that the $272 million cost estimate is based on since the route is now known.	John O'Brien	11/26/12

Comments: Meeting minutes were recorded based on the understanding of the author. Please contact the author within three days if you have any different understanding of the meeting. These minutes will be considered approved unless comments are provided within three days.

CITY OF FLINT WATER SUPPLY ASSESSMENT

KWA Discussion/Questions for the November 20, 2012 Meeting

1. Is the maximum day demand of 18 MGD for Flint the maximum day demand (MDD) throughout the 25 year planning period? If not, what is the 25 year projected MDD?
2. Copy of the intake contract documents and engineer's estimate.
3. Documentation of the Flint WTP improvements required and cost estimate.
4. Confirm Flint's allocated percentage of the KWA capital improvements (30%?).
5. Copy of the proposed KWA operating agreement for Flint.
6. What is the annual operating agreement adjustment projected for the 25 year planning period?
7. Need the route of the pipelines and the locations of the facilities proposed. Purpose is to identify constraints that impact costs (i.e., utilities, environmental (e.g. wetlands), easements, etc.).
8. KWA's initial charge to Flint is based on a 12 MGD maximum day demand. What is the basis of this number? Are there population projections and water use figures available that were used to determine the Flint demand for the 25 year planning period?
9. Is there a transition plan and cost during construction of the KWA system identified?
10. The October 4, 2012 Preliminary Engineering Report Update states: "no backup power is planned for the pumps" (LHPS) and "No backup power is planned for pumping" (IPS). In case of power loss, how would Flint supply its customers?
11. The latest plan shows only a 5 million gallon ground reservoir is planned for balancing between LHPS and IPS. How is redundancy maintained?
12. Related to the construction cost:
    a. Does it include an additional traffic lane since the construction will occupy half the right of way?
    b. Does it include costs/fees for permit requirements such as inspection cost by the jurisdictional authorities? As a point of reference, the permit fee costs for the Flint Transmission System came out to be $5.8 million.

Comments: Meeting minutes were recorded based on the understanding of the author. Please contact the author within three days if you have any different understanding of the meeting. These minutes will be considered approved unless comments are provided within three days.

c. Does the cost of the steel pipe segments include corrosion protection measures such as anode stations and related O&M?
d. SCADA monitoring stations require power. Is the cost of bring power to the SCADA stations included? Again, as a point of reference the for the Flint Transmission System we estimated $800,000 for power to SCADA and valve operators.

13. The Flint River is identified as a backup: At what capacity? MDD or emergency supply?
14. Where did the 40 years come from (Flint hostage to Detroit)? DWSD's new contracts are 30 years with openers to revise terms of supply (volume and pressure) after the first two years, then three years, and then in five year increments thereafter.

Comments: Meeting minutes were recorded based on the understanding of the author. Please contact the author within three days if you have any different understanding of the meeting. These minutes will be considered approved unless comments are provided within three days.

Your candidate would be a good choice if I do not get any other ideas by next Monday we will pass it on to the director and staff. If we approve it plan on meeting them at the plant and you may have to develop directions to get them from their first stop to the second.

Dear Mr. Kroft:

SUBJECT: Flint Cross Connection Control Program

This letter confirms my site visit on April 29, 2015, with Mr. Glen Thomas, Utilities/Cross Connection Division Inspector for the city of Flint. Mr. Stephen Busch from our office was also present. The purpose of the visit, in part, was to discuss the city's Cross Connection Control Program (CCCP).

The city of Flint has made significant progress in recent years regarding the implementation of the city's approved CCCP. This effort has included identification of accounts, inspection and re-inspection of accounts at the approved frequencies, and ensuring the testing of backflow prevention assemblies in accordance with approved frequencies. However, the city's most recent report of annual CCCP activities for 2014 indicates a significant decrease in these activities below minimum requirements, and this deficiency must be address.

Our office fully recognizes the recent staffing loss of the city's previous plumbing inspector and the importance of these plumbing inspection services in providing public health protection, but these activities should not be borne at the cost of the city's CCCP and the protections it provides. Given the bacterial detections that occurred in the city's water distribution system in August and September 2014, along with customer complaints regarding aesthetic water quality, the need for protection through cross connection control are very evident.

We also realize that implementing a CCCP of for a community water system of this magnitude requires a significant commitment of time and personnel. We encourage the city to review CCCP staffing needs and authorize the workforce necessary to comply with the city's approved CCCP requirements.

Should you require further information, please contact me at the telephone number below; via e-mail at prysbym@michigan.gov; or Department of Environmental Quality, P.O. Box 30242, Lansing, Michigan 48909.

Dear: Mr. Wright

Subject: Water Treatment Plant (WTP) Fluoridation

This letter, per your request, is being written to confirm the Department of Environmental Quality's (DEQ) position concerning the suspension of the application of fluoride until June 2014. Fluoridation was instituted in Flint approximately 50 years ago in order to increase the level of dental health protection.

While the DEQ supports fluoridation as the primary means to provide optimal dental health protection, we concur with the temporary interruption in fluoridation. This will allow WTP operators to focus on meeting the regulated drinking water standards and to increase proficiency in full-time WTP operation. The public health benefit of fluoridation is gained with long-term use and is not immediately compromised by a short-term interruption in application.

The focus on WTP operation is essential in meeting the regulated drinking water standards; thus, the city may suspend fluoridation until June 1, 2014. Please contact our office if fluoridation cannot resume by this date.

If you have any questions, feel free to contact me at (517) 290-8817; prysbym@michigan.gov; or Department of Environmental Quality, Office of Drinking Water and Municipal Assistance, Lansing District Office, 525 West Allegan Street, 1st Floor South, P.O. Box 30242, Lansing, Michigan 48909-7742.

Flint, Michigan 48502

WSSN: 02310

Dear: Mr. Johnson

Subject: Act 399 Capacity and Reliability Requirements

This letter, per your request, is being written as verification that the City of Flint water system is currently in compliance with required capacity and power service reliability requirements under the Michigan Safe Drinking Water Act and Administrative Rules, Supplying Water to the Public.

The required capacity of a waterworks system as established in Rule 1204 (R 325.11204) required sufficient capacity to meet approved finished water supply requirements, and is based upon the combination of the following options:

a. Rated capacity of an approved surface water supply or complete treatment system;
b. Firm capacity of approved groundwater supply;
c. Available contracted capacity that can be delivered from another public water supply;
d. Excess finished water storage capacity.

Under the first option listed above, the City's baseline water withdrawal capacity from the Flint River, and rated capacity of the City's water treatment plant (WTP), both exceed its finished water supply requirements. The rated capacity of a complete treatment system is established under Rule 1006 (R 325.11006). In accordance with this rule, the Department of Environmental Quality (DEQ) has established a rated capacity of 36 million gallons per day for the City's WTP, which again far exceeds current and future finished water supply requirements for the City's service area.

In addition, while capacity under item d above for excess finished water storage has not been established, the City currently has enough finished water storage to supply more than 2 days of normal finished water supply requirements

Rule 1206 (R 325.11206) requires water systems to provide a means to continuously supply fully finished water during normal power service interruption. The City's WTP is now equipped with a redundant electrical system that includes provisions for stand-by power generation; thus meeting this requirement.

While additional means to meet the above requirements for capacity and power interruption can be provided through contracted interconnections with other water systems, the City has demonstrated compliance with these requirements without such means. However, the DEQ still supports and encourages such interconnections be maintained for emergency purposes as an additional barrier to help maintain public health protections. While these emergency

Subject: RE: City of Flint emergency services contractor

Mike,

I didn't review the RFP, but the contractor should have to demonstrate some long term history of doing this type of work and having some other municipal references. (No good ol' boys club, or brothers-cousins-boyfriends contractors)

The City may also want to do a comparison of what their internal costs would be for the work. (I'm sure the DPW union will already be requesting this)

I am also in agreement with the responses from Pat and Richard.

I pretty much agree with Pat except I would expect that the OIC for a distribution system would be providing oversight for the repair/maintenance crews even if they are "contract employees." That may not necessarily mean he's standing over the ditch in every case, but he should be there for major jobs and there should be periodic reviews of procedures and protocols that are being followed in the field. And he is certainly there to answer any questions or deal with unusual circumstances. I would also say that you could make that a point of emphasis in your discussions with the city about contractual services. Either the contractor should have an S-1 operator or they agree to follow city spec's and be subject to unannounced onsite inspections.

Subject: RE: City of Flint emergency services contractor

Hi Mike,

I'm not aware of any large water supplies like Flint that contract with outside companies for main/hydrant repairs and shut-off services. However, you may wish to post this question on the Team Room page to see if any other engineers have experience in this type of arrangement.

I think you raise some valid concerns about outside parties being able to repair breaks, especially about the testing (flushing, disinfection, sampling, etc.) that may be necessary after a main repair. As you know, it's not a one-size fits-all protocol and greatly depends on if the main was repaired under pressure or no pressure.

I don't think we can require the contractors to have licensed operators since the Operator Cert rules of Act 399 only require the OIC and designated backup to be licensed. DWSD has several crews that their only job is to find and repair main leaks/breaks. I'm not 100% sure, but I bet that very few if any one those guys have distro licenses and its highly unlikely that the OIC is providing oversight on each job.

I think we can raise the question to Flint about proving oversight by a city employee/licensed operator when the outside contractor is on site to see what they say, but my guess is that they are going to balk since that will cost them staff time and money.

pat

Subject: FW: City of Flint emergency services contractor

I am a bit concerned about the city of Flint considering the idea of privatizing water distribution system repairs. I am not aware of other communities that utilize outside contractors on the scale of systems like Flint. I have a few very small rural communities (ie village of Metamora) who contract with a company (United Water in Metamora's case) to operate and maintain the water system. United Water provides certified contractors. These independent contractors may some limited ability to conduct emergency repairs but it has been my experience that they contract out watermain repairs. The contract operator's role is to oversee the work to insure that proper procedures are followed (isolation, flushing, disinfection, sampling, notification, etc.).

Back to Flint.....my first take is that any outside vendor who will be conducting emergency services such as repairing broken mains and appurtenances should hold some level of water distribution certification. Although requiring them to hold an S-1 license may be asking too much.....some level of certification makes it more likely that contractor is aware of the proper procedures and the need to protect public health.

Other items:

- Require oversight of repairs by certified Flint water utility operator
- Security issues – vendor must constantly have access to as-built plans, general plan, access to Water Service Center
- Conformance to Flint standard specs – again verified by proper oversight
- Changes the city's focus trying to re-establish a "well-operated" water utility

If you are aware of other utilities of this scale that privatize emergency repairs, please share that with me. Also, if there are other items or concerns that this could raise, feel free to add them. Thanks.

Subject: City of Flint emergency services contractor

Hello Mike. I have been directed to develop an RFP to have outside vendors under contract with the City for emergency services. The work could include anything from residential emergency turn offs to Main break repairs. Among the questions I have is what standards or qualifications would the State require of vendors? Also, how do other communities ensure adherence to State drinking water standards when vendors are performing the services. I have attached a general scope of services we intend to put out for bid. Your input would be greatly appreciated. Give me a call when you get a chance

WSSN: 2320

Dear Mr. Kroft:

SUBJECT: Flint Water Treatment Plant – Future Operation

This letter confirms our May 1, 2012, meeting with you, Mr. Daugherty Johnson III, Utilities Administrator, Mr. Brent Wright, Water Plant Superintendent, and other water utility operators. Mr. Patrick Cook, Treatment Specialist, from the Department of Environmental Quality (DEQ), also attended the meeting.

The purpose of the meeting was to discuss options for blending treated water from the Flint River with water purchased from the Detroit Water and Sewerage Department (DWSD) or blending Flint River water with raw water purchased from the Karegnondi Water Authority (KWA) and subsequent treatment at the Flint Water Treatment Plant (WTP).

The city of Flint may elect to utilize their WTP for the blending of treated water from the Flint River with water purchased from DWSD or KWA provided that all applicable drinking water standards are maintained. Also, the city is encouraged to produce and distribute treated water that is comparable to the aesthetic quality of water purchased from DWSD. Various treatment parameters discussed in the meeting that the Flint WTP will be required to meet are listed in the bulleted items below.

- CT (disinfectant concentration times total contact time through the treatment process) must be maintained to provide not less than 99.9% (3-log) removal of giardia and not less than 99.99% (4-log) removal viruses.

- The residual disinfectant concentration in the water entering the distribution system shall not be less than 0.2 milligrams per liter for more than 4 hours.

- Filter effluent turbidity (combined filter effluent); Not less than 95% of the measurements taken each month shall be less than or equal to 0.3 ntu. Also, at no time shall the turbidity level exceed 1 ntu.

Subject: Media Inquiry - Flint WTP Engineering

I received a call this morning (July 8) from Dominic Adams, Flint Journal/Mlive. I called him back with Mike Prysby, District Engineer sitting in on the call.

Mr. Adams had obtained information that the City of Flint was contracting some engineering work for the Flint WTP, and the work was in part to potentially use the Flint River as a primary drinking water source.

I informed Mr. Adams that the City of Flint receives treated water from DWSD and has been since the 1960's, but has had the WTP available for reliability should the single transmission line system from DWSD fail. In an emergency the Flint WTP is already approved to use the Flint River for source water and is designed to meet all drinking water standards and public health requirements.

I also informed Mr. Adams that the engineering work in question would be to primarily enhance treatment capabilities beyond minimum requirements for the purpose of softening to provide customers with water quality consistent with what they already receive from DWSD. Some equipment for softening is already in place, but under emergency operation would not normally be used due to the time required for startup and fine tuning.

Mr. Adams asked whether the DEQ has approved or signed off on the proposed engineering work and on allowing the City of Flint to use the River as its source water. I explained that the ODWMA has not received a construction permit application for such work at this time, and that one would be required. I also indicated to Mr. Adams, that regardless of the source water, the City of Flint would be required to meet all applicable Drinking Water Standards and public health requirements and again that the WTP is already approved as a redundant supply to use the Flint River as a source water meeting all drinking water standards and that the WTP undergoes test runs on a quarterly basis to maintain the WTP.

Mr. Adams asked for more specifics regarding the treatment process and I explained that the removal of hardness for aesthetic water quality at this WTP is called lime softening.

Mr. Adams also inquired about the City being able to use the Flint River after the contract with DWSD terminates, and I indicated that may be one option, but they could also continue to purchase treated water from DWSD.

In Mr. Adams voicemail he mentioned a variance to use the Flint River, and I reiterated that there is no "Variance", but that the WTP has been constructed and approved to treat water from the Flint River to appropriate standards as needed.

Let me know if you have any questions.

Stephen Busch, P.E.
Lansing and Jackson District Supervisor
Office of Drinking Water and Municipal Assistance
MDEQ
517-643-2314

- The fluoride concentration in Flint's finished water must remain comparable to the fluoride concentration in DWSD's water.

- Suggested Practices recommends, and we fully endorse, monitoring WTP filters and plant tap for total colifom bacteria on a daily basis. In addition to plant tap monitoring, a protocol should be established for monitoring both treated water components prior to blending.

- Finished water must meet all other applicable Maximum Contaminant Levels for organic and inorganic parameters.

Based upon the 2007 Water Treatment Plant Sanitary Survey and the results of the most recent WTP test runs, we are confident that the WTP can meet the operational parameters discussed above. Given the installation of intermediate chlorination and improved ozone residuals, Flint's CT calculation will need to be updated.

Since Flint was not required to conduct the initial round of source water monitoring for cryptosporidium, treatment classification as part of the Long Term 2 Enhanced Surface Water Treatment Rule requirements has not been determined for the WTP. The next round of cryptosporidium monitoring begins in 2015 and subsequent bin treatment classification for Flint will be determined by 2017 (after completing 24 months of monitoring). Additional treatment for cryptosporidium may be required depending on the monitoring results.

Also, since DWSD would no longer be Flint's sole source of water, various water distribution system programs including Flint's Bacteriological Monitoring, Lead and Copper, and the Stage 2 Disinfectants and Disinfection Byproducts monitoring programs will change. Specific changes to these monitoring programs will be discussed in more detail after the city identifies the future operation of the Flint WTP.

The DEQ has no objection to blending Flint River water with water purchased either from DWSD or the KWA. This type of operation will place Flint's WTP into service on a full-time basis and be of benefit in several ways. Fulltime operation will help to ensure proper function and optimization of treatment while allowing WTP operators to accrue additional experience at operating and monitoring all unit processes. Fulltime operation also helps to keep treatment equipment and their components in a reliable state of operation.

Finally, a question was raised as to the extent that the city of Flint will be required to provide a full-time back-up water supply to the city and Genesee County. As we discussed, the average day demand (with restrictions on nonessential water use) for the combined needs of Flint and Genesee County will need to be met. Both capacity and hydraulics (transmission capabilities to Genesee County) need to be determined, as part of a basis of design towards proposing a full back-up water supply for both Flint and Genesee County.

Should you require further information, please contact me at the telephone number below; via e-mail at prysbym@michigan.gov; or Department of Environmental Quality, P.O. Box 30242, Lansing, Michigan 48909.

Sincerely,

Michael F. Prysby, P.E.,

December 21, 2011

Mr. Michael K. Brown, Emergency Manager
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

Dear Mr. Brown:

SUBJECT: Water Distribution System Operator Certification;
City of Flint; WSSN 02310

The purpose of this letter is to inform you of an operator certification deficiency that the City of Flint (the City) has not resolved concerning oversight of the city's water distribution system. Specifically, the Flint water distribution system must be overseen by a water distribution system Operator-in-Charge (OIC) having an S-1 drinking water certification. This deficiency began on July 31, 2011, when the city's S-1 certified OIC, Mr. Michael Brown (Utilities Administrator) retired.

The City was informed in our August 11, 2011, letter (copy enclosed) of the need to designate a new S-1 certified OIC for the water distribution system. The water distribution system OIC would be in overall charge of the water distribution system and would be responsible for making decisions regarding the daily operational activities of the water distribution system. Under standard operation, the water distribution system OIC shall be employed and available on a daily basis to oversee records maintenance and analysis, planning, monitoring, construction, and maintenance and to supervise and direct staff responsible for daily operations.

The City was offered the option to retain a temporary OIC, for short term operation, in the event that an S-1 certified OIC was not available. The temporary OIC would allow the City to remain in compliance with the S-1 certification requirement while the City either recruited a replacement or promoted an existing staff member to the OIC position. If the City was to retain a temporary OIC, we were to review a proposed scope of services prior to the City entering into a contact. If the City did not desire to promote a staff member to the position of OIC, then the City was to immediately pursue hiring a full-time OIC, such that the OIC was on staff within 6 months (February 11, 2012). To date, we have not received any communication from the City indicating that corrective action has been taken to resolve this deficiency.

In accordance to Section 9 (5) of the Michigan Safe Drinking Water Act, 1976 PA 399, as amended (Act 399) and the Administrative Rules, "A public water supply shall be under the supervision of a properly certified operator as specified in the rules." R 325.11905 (1) of the Administrative Rules states "Any waterworks system or a portion of a system which has been classified in accordance with R 325.11901 or R 325.11902 shall be under the supervision of an operator in charge certified in the system classification as specified in these rules." In accordance with R 325.11902, the City's water distribution system has an S-1 classification.

We are requesting that the City provide us a written response to this letter by January 15, 2012, as to how the deficiency in the operator certification requirements will be corrected by the February 11, 2012, deadline. The response should include a schedule by which compliance is to be achieved. Finally, we must also affirm our position that if the City does not intend to promote an existing staff member (currently holding an S-1 certification or able to obtain an S-1 certification within the next exam cycle) to the OIC position, then the City must have a newly hired S-1 OIC on staff by no later than February 11, 2012. Failure to correct this deficiency may result in escalated enforcement action.

Should you require further information, please contact me at the telephone number below; via e-mail at prysbym@michigan.gov; or Department of Environmental Quality, P.O. Box 30242, Lansing, Michigan 48909.

Sincerely,

Michael F. Prysby, P.E.,

Met w/ G. Eason & M. Brown on 10/13/2011 to discuss temp OIC reqs.

August 11, 2011

Mr. Gregory A. Eason, City Administrator
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

Dear Mr. Eason:

SUBJECT: Water Distribution System Operator Certification, City of Flint

It was brought to our attention that the city of Flint's water distribution system Operator-in-Charge (OIC), Mr. Michael Brown (Utilities Administrator), has retired from the city effective July 31, 2011. Mr. Brown's retirement raises the issue of operation and maintenance oversight of the Flint water distribution system by an S-1 certified operator.

By definition, the water distribution system OIC is a properly certified operator who is designated by the city as the responsible individual in overall charge of the water distribution system and who makes decisions regarding the daily operational activities of the water distribution system that will affect the quality or quantity of drinking water. Under standard operation, the water distribution system OIC shall be employed and available on a daily basis to oversee records maintenance and analysis, planning, monitoring, construction, and maintenance and to supervise/direct staff responsible for daily operations. Specifically, the city of Flint is required to have an S-1 certified operator be designated as the OIC and oversee the operation and maintenance of the water distribution system.

The city will need to designate a new water distribution system OIC with an S-1 certification. The city also needs to designate a back-up operator. Enclosed is an Operator and Back-up Operator Designation Form. Please complete the form and return it to our office.

Next, in the event that an OIC is not available to meet the standard operation criteria, it will be acceptable, for short-term operation, for the city to recruit a replacement or promote a staff member to the OIC position. During this interim period, the city must retain a temporary OIC having an S-1 certification to visit the water supply system at least twice a week, to be on-call 24 hours per day, and supervise/direct staff responsible for daily operations. The following conditions also apply:

- If the city wishes to promote a staff member to be the OIC after the staff member has achieved proper certification, this individual must first qualify to write the S-1 certification examination when it is next offered (November 2011). If this individual fails the examination, the city must immediately pursue the hiring of a full-time OIC.

- If the city does not desire to promote a staff member to be the OIC, then the city must immediately pursue hiring a full-time OIC. The OIC must be on staff within 6 months.

Finally, if the city retains a temporary OIC, we would appreciate an opportunity to review the scope of services if the city enters a new contract.

Should you require further information, please contact me at the telephone number below; via e-mail at prysbym@michigan.gov; or Department of Environmental Quality, P.O. Box 30242, Lansing, Michigan 48909.

Sincerely,

Michael Prysby

June 20, 2011

Mr. Brent Wright, Plant Supervisor
City of Flint, Water Plant
4500 North Dort Highway
Flint, Michigan 48505

Dear Mr. Wright:

SUBJECT: City of Flint Water System

This letter confirms my visit you and Mr. Michael Glaskow on June 9, 2011. The purpose of the visit was to conduct routine water system surveillance and to observe a routine water treatment plant (WTP) test-run. The status of various water related concerns were discussed during the visit and these are discussed in more detail below.

1. A routine WTP test-run was being conducted and, based upon the site visit, finished water turbidity and total coliform treatment objectives were being achieved. Specific operating parameters along with an overall summary of the test-run will be provided to us in the test-run report. Finally, we have not received the reports for the WTP test-runs completed since 2010. It is our understanding that three test runs were performed in 2010 and two (including the current test run) in 2011. Please provide us with a copy of these WTP test run reports. Finally, we are pleased with the commitment put forth to conduct routine WTP test-runs and we encourage the city to maintain this level of commitment.

2. WTP staff are continuing to work on the WTP Standard Operating Procedure (SOP) for routine test-runs and pipeline emergencies. Please provide us with a copy of the SOP after it is completed.

   Next, WTP staff and Water Service Center (WSC) staff are working to complete the water system Emergency Response Plan (ERP). Again, please provide us with a copy of the ERP for our review and approval.

   Finally, a mock Improved Explosive Device (IED) Attack on the Flint WTP was conducted on May 12, 2011. The mock exercise tested the response, coordination and communications between the City of Flint, Genesee County first responders, and state departments. The DEQ, however, was not notified of the mock incident due to a breakdown in communication during changes in

emergency oversight at the WTP. It is our understanding that WTP staff are making further changes to the water system ERP to include specific instructions confirming that all critical contacts have been notified.

3. Based upon our discussion, Phase II of the reliability study is nearly complete. We look forward to reviewing the second phase of Flint's reliability study when it becomes available. Finally, it is also our understanding that the amended Phase I report will be included with the Phase II report.

4. The 2011 Drinking Water Infrastructure Needs Survey was sent to the city in March 2011. It is our understanding that WTP and WSC staff are working to complete the survey by the end of June. We encourage the city to complete and return the survey to our office within the next several weeks.

Finally, the city of Flint continues to investigate its long-term source for drinking water. Options for future water supply source include; continued service from Detroit, establishing a new surface water source from Lake Huron – Karegnondi project (as a joint venture with other communities), or utilization of Flint's existing resources. As we discussed in our previous letter, each option will require a certain level of WTP and pumping station operation. Please keep us updated concerning the city's progress towards identifying the most practical alternative for its long-term source for drinking water. We will also to continue to meet with you and your water department staff on a quarterly basis to review the issues and the efforts concerning the city's water system.

Should you require further information, please contact me at the telephone number below; via e-mail at prysbym@michigan.gov; or Department of Environmental Quality, P.O. Box 30242, Lansing, Michigan 48909.

Sincerely,

Michael Prysby

February 17, 2011

Mr. Gregory A. Eason, City Administrator
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

Dear Mr. Eason:

SUBJECT: City of Flint Water System

This letter confirms our meeting on February 10, 2011, with Mr. Mike Brown, Mr. Brent Wright, Mr. Rick Freeman from Rowe Incorporated, and yourself at the Flint Water Treatment Plant (WTP). The purpose of the meeting was to conduct routine water system surveillance. The status of various water related concerns discussed in our meeting and further actions necessary to correct them are discussed in more detail below.

- **Water system Emergency Response Plan (ERP)/WTP Standard Operating Procedure (SOP)** – A draft copy of the city's water distribution system contingency plan and the WTP SOP for routine test-runs and pipeline emergencies was provided to us. Several questions/comments were noted during our review of each plan and were discussed during the meeting. The questions/comments were noted on each document and provided to Mr. Wright. The questions/comments should be answered as part of preparing final versions of each plan.

  Next, changes to the Administrative Rules of the Michigan Safe Drinking Water Act, 1976 PA 399, as amended, now require an ERP in place of the contingency plan. The ERP provides an outline to follow in the event of a water related emergency (loss of pressure, contamination, etc.). The ERP is similar to a water system contingency plan; however, various types of programs/plans pertaining to water utility operation need to be referenced in the ERP. An electronic copy of the ERP template was sent to Mr. Wright and can be used for preparing Flint's ERP. We will review the completed ERP during our next routine surveillance visit.

  Finally, we concur with the idea of dividing the WTP SOP into two separate SOPs for each mode of WTP operation. Specifically, a separate SOP will be established for routine test-run operation and emergency plant production. Please provide us with a copy of each SOP when they are completed.

- **Reliability study** – Based upon our discussion, Phase II of the reliability study is nearly complete. Phase II is to include various alternatives for recommended capital improvements. Asset management principals will also be included. We look forward

to reviewing the second phase of Flint's reliability study when it becomes available. It is also our understanding that the Phase I report was amended following our review comments. Please provide us with a copy of the amended Phase I study.

- **Booster pumping station deficiencies** – Based upon our discussion, improvements to the Torrey Road and Cedar Street pumping stations will be resubmitted as part of Flint's 2011 Drinking Water Revolving Fund (DWRF) application. A revised project plan that clearly identifies the need for the station upgrades, along with all of Flint's other 20-year water system needs, will need to be prepared. The project plan will also include some distribution system improvements. The city should also take the opportunity to utilize the reliability study for additional documentation in support of the projects that are included in the project plan. Finally, given the uncertainty of Flint's long-term pumping needs at Pump Station No. 4, no immediate improvements are planned for this facility.

  While there is uncertainty over the degree of long-term use of Pump Station No. 4, this station is critical for today's water supply operations. Continued effort is needed now to ensure adequate reliability of Pump Station No. 4 and its respective storage reservoirs, especially during emergency operation.

- **WTP Test Runs** - Routine WTP test runs continue to be conducted on a quarterly basis. Each test run increases the experience and confidence of plant operators to further assure that plant production water meets all applicable drinking water standards. Based upon our discussion, treatment continues to improve with each test run. Given the importance of maintaining the familiarity with treatment plant operation, and the potential of needing to place the WTP into emergency operation to distribute treated water to the public, WTP test runs need to continue on a quarterly basis. Finally, please provide us with copies of the 2010 WTP test run reports

- **Operator Certification** – WTP operator Mr. Mike Glaskow has obtained the F-1 certification and has been designated as the Operator-In-Charge (OIC). As OIC, Mr. Glaskow will be responsible for reviewing and signing the following monthly/annual reports:

  - Monthly Operation Reports
  - Consumer Confidence Report and Certification Form
  - Lead/Copper Reporting Form
  - Annual Pumpage Report

  Next, with Mr. Glaskow obtaining the F-1 certification, the city has achieved full compliance with the F-1 certification requirement. It is also our understanding that the city has discontinued their mutual aid agreement with Genesee County for operator assistance during routine test runs; however, the county is available to assist, as needed, during emergency operation. We encourage the city to maintain the availability of assistance from Genesee County during emergency operation.

- **Infrastructure Needs Survey** - The 2011 Drinking Water Infrastructure Needs Survey will be sent to Flint in March 2011. We encourage the city to complete and return the survey to our office. As always, we are available to meet with you to discuss various water related projects that could be included in the survey as part of

Flint's overall 20-year needs. The city should also take the opportunity to utilize the reliability study for additional documentation in support of the projects that are included in the needs survey. Finally, our department will be providing several training sessions to assist in completion of the 2011 survey. The city will be provided with additional information pertaining to the training sessions when it becomes available

- **Future Water Source** – The city of Flint is faced with the challenge of determining its long-term source for drinking water. Options for future water supply source include; continued service from Detroit, establishing a new surface water source from Lake Huron – Karegnondi project (as a joint venture with other communities), or utilization of Flint's existing resources. Each option will require a certain level of WTP operation. The level of treatment and scope of improvements at the WTP will need to be carefully evaluated as part of selecting the most suitable option. Other important factors include; short-term source(s) of supply, residuals management (correcting the violations at the Bray Road sludge lagoons vs. on-site treatment), and available source capacity (Lake Huron supply and Flint River watershed).

We appreciate having the opportunity to meet with you to discuss the status of Flint's water system and the challenges that lie ahead. Finally, we will to continue to meet with you and your water department staff on a quarterly basis to review the issues and the efforts concerning the city's water system.

Should you require further information, please contact me at the telephone number below; via e-mail at prysbym@michigan.gov; or Department of Natural Resources and Environment, P.O. Box 30242, Lansing, Michigan 48909.

Sincerely,

Michael F. Prysby, P.E., District Engineer

February 17, 2011

Mr. Michael Brown, Utilities Administrator
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

Dear Mr. Brown:

SUBJECT: Customer Site Piping

The Department of Natural Resources and Environment, Environmental Resource Management Division (DNRE), has received a schematic from Alpine Engineering, Inc., detailing a proposed watermain relocation within the city of Flint. An existing 8-inch main is to be relocated to allow for construction of the proposed Department of Human Services (DHS) office building. The question was raised as to whether a construction permit would be needed to relocate the existing main.

Based upon the schematic, and that the size of the main is not being changed, a permit would not be required by our office. However, it was brought to our attention that the relocated watermain (approximately 555 feet) will be privately owned. Also based on the drawing, the private main (referred to as "customer site piping") will be connected to the city of Flint's water distribution system at both ends. Our primary concern with customer site piping with more than one connection to the municipal water system is establishment of a "flow through" situation. As water enters a private main, the utility gives up control of the water and it has the potential to re-enter the municipal system at the other connection(s). There is the potential for the degradation of water quality in a privately owned system, thus the DNRE does not allow private ownership of watermains where flow-through situations can exist. Finally, failure of the utility to acquire ownership of customer site piping where a "flow through" condition exists, is a violation of Section 325.1005a, Sec. 5a (1) of the Michigan Safe Drinking Water Act 1976 PA 399, as amended, Michigan Compiled Law 325.001 *et seq.*

The watermain proposed to serve the DHS building needs to become publically owned and maintained by the city of Flint. This will call for the establishment of a public watermain easement or right of way in this area. Any easements that are obtained need to be documented and a copy provided to us.

Next, if the city of Flint is unable or unwilling to assume ownership of this watermain, then it will remain customer site piping. We are in the position to allow a utility to make more than one connection to customer site piping provided that double check valve assemblies are installed at each point of connection. These devices will need to be located within a concrete vault to ensure proper operation and protection. We would also suggest that a master meter be installed in the vault. Adequate valving must be installed to allow for removal of the device during maintenance.

Finally, in lieu of installing double check assemblies, the city of Flint may elect to establish an operating/maintenance agreement with the owner of the customer site piping. The contract would allow the city to have sufficient control of the main in terms of maintenance and repair without actually owning it. Enclosed is an example of an operating agreement established between the owner of customer site piping and a municipality. If the city elects to establish an operating agreement, a copy of the operating/maintenance contract needs be sent to us for review and comment.

Should you require further information, please contact me at the telephone number below; via e-mail at prysbym@michigan.gov; or Department of Natural Resources and Environment, P.O. Box 30242, Lansing, Michigan 48909.

Sincerely,

Michael F. Prysby, P.E.

Dear Mr. Eason:

SUBJECT: City of Flint Water System

This letter confirms our meeting on March 30, 2010 with you, Tom McCabe, Michael Brown and Brent Wright. Mike Prysby from our office was also present. The purpose of the meeting was to discuss the overall status of the city of Flint water system and some of the items of immediate concern. An information packet containing a summary outline, recent correspondence, and copies of the Flint Water Treatment Plant and Distribution System Sanitary Surveys was provided to you during the meeting.

We appreciated the opportunity to meet with you, and we look forward to working with you and your water utility staff toward accomplishing additional water system improvements. The city has made good progress over the last year or so, and we hope the ongoing efforts will continue.

Finally, we discussed the possibility of meeting with you and available members of the Flint city council at the Flint Water Treatment Plant during a routine test run to help reinforce the importance of the treatment plant and to answer any questions about the facility or the water system. Please let us know if you wish to pursue this type of visit.

Please feel free to call if you have any questions concerning the topics that were discussed during the meeting. You may contact Mike Prysby at 517-335-6122 or you may contact me at the number provided below.

Sincerely,

Dear Mr. McCabe:

SUBJECT: City of Flint Water System
Sanitary Survey Update
Water Treatment Plant, Water Distribution System

This letter confirms our meeting on December 2, 2009 with you, Michael Brown and Brent Wright. Jeff Bryson from the Genesee County Drain Commissioner's office and Rick Freeman from Rowe, Incorporated were also present. Mr. Timothy Benton from our office was also present. The purpose of the meeting was to update the City of Flint 2007 Water Treatment Plant Sanitary Survey and the 2008 Water Distribution System Sanitary Survey.

In general, each survey covers the major aspects of Flint's water system including: stand-by facilities, distribution, source capacity, and storage. The purpose of this letter is to emphasize the water related items posing the most concern. These items are discussed in more detail below.

WATER TREATMENT PLANT

1. Hamilton Dam – The city's consultant, Stantec has recommended replacement of the Hamilton Dam with construction of a new concrete spillway. Prior to completing the spillway's design, the minimum pool depth upstream of the dam necessary to allow operation of the Water Treatment Plant (WTP) at its rated capacity (36 million gallons per day (MGD) needs to be determined. It is our understanding that WTP staff will be coordinating efforts with their consultant in performing pump tests at the low service (LS) pumping station in conjunction with various levels in the Flint River to determine the minimum pool depth elevation. WTP staff also needs to either obtain or prepare the pump curves for each of the LS pumps. The pump tests at LS need to be completed since this information plays a vital role in establishing the design height of the new spillway. Also, we encourage WTP staff to take the opportunity to operate all of the LS pumps during the test to further determine the reliability of the LS pumping station. Finally, we look forward to reviewing the results of the pump test and the amount by which the river can be lowered without impacting the WTP's ability to operate at its rated capacity.

2. High Service (HS) Pumping – HS pumps #1 and #2 at Pump Station No. 4 are not available for service. The remaining pumps (HS Pumps #7, #8, and #9) provide a total and firm (available capacity with the largest pump out of service) HS pumping capacity of 46 and 26 million gallons per day (MGD) respectively. Based upon our discussion, HS Pumps #7, #8, and #9 are in good operating condition.

   We are comfortable with the total and firm HS pumping capacity to meet Flint's water usage in the event of an emergency repair to the 72-inch pipeline. The firm HS pumping capacity, however, falls somewhat short in meeting the combined needs of Flint and Genesee County during a pipeline emergency.

   While we all agree that additional HS pumping capacity would be needed to meet the combined needs of the city and Genesee County, HS pumping capacity will be a function of the station's future level of use. The station's future level of use is uncertain at this time due to Genesee County's plan to utilize Lake Huron as their future source of water (Karegnondi Project) and Detroit's plan to provide a second transmission main from Detroit (Flint Transmission System – FTS and North Oakland Transmission System – NOTS projects). When the outcome and design of these projects become more certain, the intended future use level of HS pumping needs to be evaluated to determine the amount of HS pumping capacity that will be needed.

3. Operator Certification – We are pleased that the city has taken corrective action to address the deficiency in operation certification at the WTP. Specifically, a "memo of understanding" has been established with Genesee County that authorizes an F-1 operator from Genesee County to oversee operation of the WTP during emergency operation. It is our understanding that Dave Jansen and/or Jeff Bryson are the designated operators-in-charge (OIC) during emergency operation. Please provide us with a copy of the memo of understanding with Genesee County regarding operator oversight at the WTP. Also, operation reports specific to emergency operation of the WTP need to be signed by the designated OIC. Next, we are also supportive of F-1 oversight from the county during routine WTP test-runs and we encourage the city to continue this practice. Routine WTP operation during plant downtime can be covered with the city's current certification status. Finally, the routine monthly operation report may continue to be signed by Brent Wright.

4. Water System Contingency Plan – Based upon our discussion, WTP staff are preparing a contingency plan specific to emergency operation of the WTP. The plan identifies the parameters necessary for implementation of WTP operation and will establish a set of standard operating procedures. The plan should also take into consideration the different types of pipeline emergencies that could arise and how each scenario will affect operation of the WTP. Coordination of remedial activities between the WTP, Water Service Center (WSC), and Genesee County operators should also be outlined in the WTP contingency plan.

Next, a separate water system contingency plan specific to other types of distribution system emergencies (contamination, backflow, pressure loss, etc.) is also being prepared. This plan is being based on our contingency plan format that was provided to city earlier this year.

Finally, both contingency plans are expected to be completed by early 2010. Please send us a copy of each plan for our review.

5. Intermediate Chlorination – During 2009, the WTP was placed into emergency operation twice and treated water was distributed to Flint's water distribution system. Intermediate chlorination was added on a temporary basis in order to provide a higher level of assurance that the drinking water being supplied to the city met the drinking water standards for coliform bacteria. The benefits of intermediate chlorination were especially realized during the WTP's August – early September 2009 emergency operation. The presence of chlorine through the majority of the treatment process provided the level of assurance needed to avoid having to issue a system-wide boil water advisory.

   We strongly support WTP staff with their intent to provide intermediate chlorination on a permanent basis. Various options for intermediate chlorination including a tablet feed system (pellet or erosion type) or a small scale chlorine gas system are being investigated. Prior to installing an intermediate chlorine feed system, a completed permit application along with a proposal (plans, specs, basis of design) needs to be sent to our office. Following our review and approval, a construction permit will be issued for the proposed work.

   Finally, intermediate chlorination will require provisions for dechlorination of the filter to waste effluent. Dechlorination is necessary in order to maintain compliance with the NPDES discharge limits for the discharge of treated water to the Flint River during routine WTP test runs. WTP staff is investigating options for a dechlorination system. Finally, prior to installing a dechlorination system, a construction permit will be issued for the proposed work.

WATER DISTRIBUTION SYSTEM

1. Water System Reliability Study – Based upon our discussion and the Water System Reliability Study Project Summary, Phase I of the reliability study is expected to be completed in January 2010. Items that were completed in Phase I included a detailed water system general plan showing the locations of hydrants, valves, storage facilities, pumping stations, etc. Also completed are the updated hydraulic model and the flow tests to calibrate the model. Finally, a 6-year capital improvements plan (CIP) is being prepared as part of the first phase of the study. We look forward to receiving a copy of the first phase of study for our review and comment.

The second and third phases of the reliability study include distribution system and WTP asset management and establishment of a 20-year CIP. We encourage the city to continue to put forth the effort with their consultant towards completing the reliability study and following through with the recommended improvements.

2. Valve Program – We are pleased with the effort put forth by the WSC towards improving the water system valve program. The approximate location of all water system distribution system valves have been entered into city's GIS system and are also noted on the base map. Also, the exact location of each valve is nearly two-thirds complete.

   The next major step towards improving the valve program is to determine the operating condition of each valve and enter this information into the database system. This step will be initiated after all of the valve locations have been confirmed. Finally, the second phase of the reliability study will establish a valve maintenance program.

   We encourage the city to continue working with their consultant towards obtaining the critical information that is needed to establish a complete recordkeeping system for distribution system valves. The city will also need to determine the level of staffing that will be needed in order to maintain an adequate valve maintenance program.

3. Pumping Stations – The city has not proceeded with rehabilitation of the electrical system at the Cedar Street pump station or replacement of the Torrey Road pump station. Although the objective was to finance the project with drinking water revolving funds (DWRF) and a construction permit was issued, these projects did not proceed due to the city's current bond debt.

   While we understand the city's concern of increasing their bond debt, the condition of both stations and their limited operating reliability raises concern. The Cedar Street station's electrical switchgear is clearly outdated and needs to be replaced. Also, provisions for stand-by power were provided as part of the DWRF project. Next, the Torrey Road pump station has only one reliable pump for operation and this facility plays a critical role in providing adequate water service to the western portion of the city including the Hospital Hill area. Finally, stand-by power was also included in the Torrey Road project.

   It is our understanding that the city intends to replace the electrical switchgear at the Cedar Street PS next summer. The city is also considering rehabilitating the existing pump station at Torrey Road as opposed to constructing a new facility. The upgrades would include new pumps and motors, controls, and valving. We would be agreeable to an upgrade of the existing station based on the scope of work that was discussed. Upgrades to the Torrey Road pump station would proceed in 2011.

Finally, discharge piping and valving improvements have not been completed at the Westside PS. This work needs to be completed in order to reduce water hammer and subquent main breaks in areas downstream from the station. It is our understanding that work on the Westside PS will be proceed following completion of the work at the Cedar Street and Torrey Road PSs.

We are agreeable to the approximate timeframes to correct the deficiencies at each of the pumping stations. We would be interested, however, in receiving a schedule for each project.

It is evident that the city has taken some serious steps towards identifying various water system deficiencies and investigating corrective action options. We are also pleased with the improvement in WTP operation during 2009 and the ability of the WTP and its staff to provide an emergency supply of drinking water to the city that met all of the applicable drinking water standards.

We also wish to remind the city that much work remains to be completed. The city needs to meet the financial challenges in completing water system infrastructure projects and improving utility operations. Given the improvements made in WTP operation, operator certification, valve program, and the progress made with the reliability study, Flint's water system has improved to a **"Marginal"** rating. The amount of effort and progress that is put forth over the next 24 months, especially in the key areas discussed in this letter, will determine whether Flint's water system rating improves further or declines.

We appreciate the time taken to meet and discuss the current status of the city water system and we look forward to working with you on these water related issues. If you have any questions concerning these items or on any other water related matter, please don't hesitate to call me at the number provided below.

Sincerely,

Michael Prysby

Kurt:

Enclosed please find an executed change order number four (4) adopted February 23, 2009. Change order number four reduces the Sorenson Gross contract by $25,000.00 . The reduced amount was the cost to provide ozone electronic/computer upgrades and remote operation for the Ozonia installed ozonation system.

The City of Flint in part has contracted professional services from Motor City Electric Technologies Inc. (MCETI), to provide emergency services to the Ozonia equipment on an as needed basis. As needed services were required by the City of Flint to resolve safety emergency issues on the Ozonia equipment by a certified Ozonia contractor. In the State of Michigan, MCETI is the only certified professional service provider.

The use of the deducted $25,000.00 by the City of Flint, is to provide electrical/computer upgrades and remote operation on the installed Ozonia equipment. These changes are required for the efficient operation and Sorenson Gross couldn't provide the service. In addition, City staff will provide assistance to MCETI, on a force account basis to ensure transfer of knowledge. The total cost of the City force account and MCETI will not exceed $25,000.00

We hope to have the work completed by the end of August 2009. If you have any questions feel free to contact me at (810) 787-6537. We thank you for your attention in this matter.

Respectfully submitted,

Brent Wright

Dear Mr. Prysby:

SUBJECT: City Of Flint WTP OIC

In response to your letter of April 24, 2009, the City Of Flint is in the process of drawing up a contract with Genesee Co. WWS to obtain the use of an F1 operator. The F1 operator will oversee and advise the operation of the plant during scheduled test runs. If an emergency exists and water is introduced to the distribution system, the WTP staff will be under the direction of the OIC. The OIC will also review and sign the MOR. I believe an agreement and or contract will be signed before the June 1st dead line you imposed. The City Of Flint will send a confirmation letter and copy of the agreement upon its implementation.

Sincerely,

Brent F. Wright, Supervisor

WSSN: 2310

Dear Mr. Brown:

SUBJECT: City of Flint Water System – Operator Certification

We have been alerted to the decision by the City of Flint to end the contact with Carlyon Consulting effective May 8, 2009. The purpose of the contract was to provide the Flint Water Treatment Plant (WTP) with an interim operator in charge (OIC) having the required F-1 complete treatment certification. The service contract was established in order to allow the city to remain in compliance with the requirement for a properly certified operator at the Flint WTP pursuant to the Michigan Safe Drinking Water Act, Act 399 P.A. 1976, as amended, and the Administrative Rules.

We have worked closely with the city and WTP staff over the past few years towards obtaining a properly certified OIC. The certified OIC plays a major role in assisting the plant operators in demonstrating the WTP's ability to produce drinking water that meets the applicable state and federal drinking water standards. The ability of the WTP to produce quality drinking water is critical in the event of an interruption in supply from the Detroit Water and Sewerage Department transmission line. The city has invested over $40 million in the standby water treatment plant but highly qualified and experienced operators are absolutely essential to make the facility function satisfactorily.

We have noted that with the assistance of Carlyon Consulting WTP performance has improved during the most recent plant test-run. We have also noted that the frequency of repairs to the 72-inch diameter transmission pipeline have increased, thus the need for adequate WTP operation will always remain a concern provided that the pipeline remains the only source of drinking water for Flint.

If the city terminates the contract with Carlyon Consulting, a new OIC having a current F-1 certification should be retained as soon as possible but by no later than June 1, 2009. In addition, we would appreciate an opportunity to review the scope of services if the city enters a new contract.

If you have any questions regarding this issue or any other drinking water related matter, feel free to call me at the number provided below.

Sincerely,

Michael F. Prysby, P.E., District Engineer

March 6, 2009

Dear Mr. Prysby;

SUBJECT: City of Flint Water System

This letter contains responses to several issues discussed in your letter dated February 5, 2009. A number of items have been impacted by the recent change in Administration of the City of Flint. The City no longer employs Mr. Lyle Hippensteel. Mr. Darryl Buchanan has been reassigned within the administration. For some unknown reason, your letter dated February 5, 2009 was not delivered to Mr. Mike Brown or Mr. Brent Wright. They only became aware of its existence late last week when Mr. Rick Freeman mentioned the subject.

Mr. Brent Wright and Mr. G. Robert Carlyon have scheduled test operations of the Water Plant beginning on Monday, March 9, 2009 and concluding on Saturday, March 14, 2009. The ozone system has undergone recent reprogramming and this will be the first opportunity to familiarize the staff with the revised operational parameters. As itemized in the recent Water Plant Sanitary Survey, the two larger low service pumps (those rated at 25 MGD and 30 MGD) will be operated to determine their readiness for service. Mr. Brent Wright has successfully revised job descriptions at the Water Plant that will create an ongoing class of dual-purpose employees whose job duties will encompass both operational and maintenance activities. Several employees engaged in this training series will be applying to test for F-4 certification in May. In a continuing and expanding program of encouragement of operator training and certification, several other staff members who currently hold certifications have applied to take more rigorous exams this spring.

With the above news, Mr. Brown, Mr. Wright and Mr. Carlyon would like to invite both you and some staff member from Operator Certification and Training to accompany you during the test operation. The unique status of the Flint Water Plant in dividing its time as a treatment facility and a distribution facility spanning the conventional boundaries between Class F and Class S water facilities needs to be considered when reviewing applications for certification testing.

With regard to the water system reliability study, a City Council resolution to enter into a contract to conduct such a study and provide written reports of the results has been prepared. The initial signature and approval process is currently underway prior to submittal to the Council for approval.

The bids for the relocation and expansion of the Torrey Road Pump Station have been reviewed. The low bidder was nearly double the engineer's estimate of project cost, creating a review of the plans and specifications to trim costs. Other members of the Utilities Department staff and Rowe Professional Services have been involved in revising the plans and specifications for rebidding the project. The City of Flint remains optimistic that this project can be completed within the 2009 construction season.

The Water Service Center continues to have one employee dedicated to inputting the data collected by other members of the staff with regard to the location and condition of valves within the system.
We have attached a copy of a document prepared and provided by MDEQ to the City of Flint regarding the scope of services to be provided by the "Interim" Operator-In-Charge of the Flint Water Treatment Plant. Please use Mr. Brent Wright as your contact as the provisional Water Treatment Plant Supervisor. Mr. Wright is applying for certification as an F-2 Water Treatment Systems Operator by taking the test in May of this year. He has actively pursued the education requirements suggested by the MDEQ and is currently scheduled to take another MDEQ course next month. Because he has over nineteen years experience in the maintenance and operation of the Flint Water Plant, we feel confident in his ability to gain the appropriate certification level soon. In the meantime, Mr. Carlyon visits the facility one or more times per week routinely. He reviews the MOR, and has recently taken over a greater role in the Hamilton Dam replacement project by assisting in the development and review of a formal "Request for Qualifications" document, review criteria and a scoring matrix to allow the City to chose an engineering firm to finalize the scope of services and develop plans and specifications of the resulting construction project.

We remain confident of your assessment during the January 21, 2009 meeting that the City seemed to be making considerable progress toward upgrading the status of the water system from a regulatory compliance standpoint. We remain likewise confident that our efforts will result in a comprehensive review of the system within the upcoming year that will minimize the deficiencies previously noted and restore Flint to compliance with the appropriate regulations.

Yours truly,

Michael Brown,
Utilities Administrator
City of Flint

Brent Wright,
Provisional Water Plant Supervisor

February 5, 2009

Mr. Darryl Buchanan, City Administrator
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

Dear Mr. Buchanan:

SUBJECT: City of Flint Water System

This letter confirms my meeting on January 21, 2009 with Lyle Hippensteel, Mike Brown, Brent Wright, Robert Carlyon, and representatives from Rowe Incorporated. The purpose of the meeting was to discuss the progress that is being made by the city towards addressing the water system deficiencies outlined in the Violation Notice sent to the city on July 7, 2008 and further discussed at a meeting with you at city hall on July 28, 2008.

We received your written response to the Violation Notice on December 22, 2008. Your response which includes a summary prepared by your water department staff and consultant demonstrates that the city has made some progress towards addressing the water system deficiencies. The status of these deficiencies and further actions necessary to correct them is discussed in more detail below.

- Water system contingency plan – Based upon your response and my most recent meeting, a water system contingency plan is being developed that will reflect potential water system emergencies. In addition to addressing typical water related emergencies (power outage, large watermain break, contamination, equipment failure), the plan also needs to address emergencies associated with the 72-inch transmission pipeline and emergency operation of the stand-by water treatment plant (WTP). Finally, enclosed is a water system contingency plan format that was requested Mr. Carlyon.

- Reliability study – Rowe Incorporated has prepared a Scope of Services (SOS) for the reliability study. Based upon our review, the SOS addresses all of the suggested reliability study criteria and is acceptable. We encourage city administration to approve the SOS such that the first phase of the study can be completed by the target date of July 2009.

- Distribution operator training and certification – The city has committed to promote operator training and certification at all levels of distribution certification. We encourage the city to maintain this level of commitment.

- Booster pumping station deficiencies – The Torrey Road pump station project is out to bid and a Notice to Proceed is expected to be granted this spring. The city needs to approve the bids such that construction of the pump station can proceed this year. Next, a cost estimate is being obtained for pump discharge piping modifications at the West Side pump station to address water hammer problems. Again, this improvement at West Side needs to proceed in order to help resolve the issue of frequent main breaks that occur in the surrounding area.

  Next, while we might agree that some uncertainty may exist regarding the future long-term use of pump station No. 4 and Cedar Street pump station; these are critical, important, facilities for today's water supply operations. Additional effort is needed now to ensure adequate reliability of the both pump stations and their respective storage reservoirs, especially during emergency operation. Although we are not opposed to the idea of installing a solar powered mixing system at the Cedar Street reservoir, all options to increase the station's reliability and efficient use of the reservoir need to be investigated.

- Water system valve program – It is our understanding that the Water Service Center has located approximately 80-85 percent of the distribution system valves, and has established a database for hydrants and valves. Approximately 25 percent of the located valves need to be replaced. The city needs to continue working toward establishing an satisfactory valve program. Finally, the status of the distribution system valves and other distribution system appurtenances need to be provided to your consultant as part of the water system reliability study.

- F-1 Operator-in-Charge (OIC) – According to your letter, the city of Flint has retained the services of Robert Carlyon as the F-1certified OIC for the stand-by WTP. Please provide us with a scope of services for this contract. The scope of services should clearly identify the OIC responsibilities in overseeing WTP test runs, emergency operation, on-going operator training, and physical oversight of the stand-by WTP. Finally, the frequency of the OIC attendance or oversight should be detailed.

We appreciate the city's efforts so far to address the water system deficiencies that were listed in the Violation Notice; however, the city must remain committed towards fully correcting the problems with the public water system. Much continued effort and expenditure will be required to bring the water system back into compliance with the Michigan Safe Drinking Water Act.

Next, a method to track the corrective steps of all the water system deficiencies noted in the distribution system sanitary survey and the water treatment plant survey needs to be developed. Based upon our meeting, a spreadsheet that will list specific projects along with a milestone schedule is being developed. This spreadsheet will also update the

preliminary schedule that was provided to us last fall. Please provide us with a copy of the project spreadsheet for our review and comment.

Finally, we will to continue to meet with you and your water department staff on a quarterly basis to review the issues and the efforts concerning the city's water system. If you have any questions regarding this issue or any other water related matter, feel free to call me at the number provided below.

Sincerely,

Michael F. Prysby, P.E., District Engineer

Dear Mr. Buchanan:

SUBJECT: City of Flint Water System

This letter confirms our meeting on July 28, 2008 with you, Lyle Hippensteel, Mike Brown, Brent Wright, and representatives of Rowe Incorporated. The purpose of the meeting was to discuss the water system deficiencies referenced in Flint's July 7, 2008 Violation Notice. The Violation Notice also included Flint's 2008 Water Distribution System Sanitary Survey.

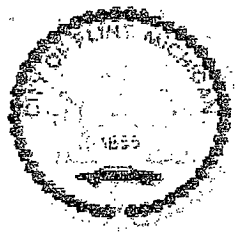
It was good to hear that you are committed to taking action to address the water system deficiencies that were listed in our agenda for the meeting. We are requesting that you or someone from the staff provide us with a written summary outlining the initial steps that the city will be taking to address these items. It is important that we hear from the city in writing, and especially that you notify us as to meeting the requirement for an F-1 certified operator at the water treatment plant.

Next, the city will need to develop a method to track the many items of not only the distribution system sanitary survey but also the water treatment plant survey. We also need to discuss the many items and come to agreement on a schedule for the city to address them.

Finally, a package of previous correspondence discussing Flint's water system deficiencies was provided to you.

As was also discussed, we believe it would be helpful to meet with you and your water department staff on a quarterly basis to review the issues and the efforts concerning the city's water system. If you have any questions regarding this issue or any other water related matter, feel free to call me at the number provided below.

Sincerely,



Michael Prysby

Anthony Adams
Deputy Mayor
City of Detroit
Water and Sewerage Department
735 Randolph Street, Room 506
Detroit, MI 48226-2830

Dear Mr. Adams:

This letter is a follow-up to the County of Genesee's letter to the Department on June 3, and Mr. Mercado's response of June 12, 2008.

The City of Flint in concert with Genesee County is requesting to begin the process for a new water contract with the City of Detroit. It is our expectation that we will explore all options for water supply between the communities. The following is a list of items we wish to cover:

1. New contract with options to have a mutual aid agreement.
2. Option to purchase pipeline from Imlay City to Genesee County.
3. Option to purchase raw water from Port Huron.
4. Option to purchase capacity in the Detroit system.

As you know, our biggest hurdle to a renewed agreement is the distance and elevation multiplier that is applied in the rate model. We believe the multiplier as applied does not reflect a true cost of service and, therefore, increases our costs significantly higher than the benefit received.

As we are working in concert with Genesee County and since they have been working with your Department over the last two years on this issue, we have no objections to you continuing this process through their office. I have confidence that they will work in the best interest of all county residents including the City. Therefore, please schedule a meeting through the County.

Sincerely,

Donald J. Williamson

CERTIFIED MAIL

VIOLATION NOTICE

Mr. Daryl Buchanan, City Administrator
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

WSSN: 2310

Dear Mr. Buchanan:

SUBJECT: City of Flint Water System
2008 Water Distribution System Sanitary Survey Update

This letter confirms my visits on April 11, 2008, April 15, 2008, and April 22, 2008 with Michael Brown, Brent Wright, and Glen Thomas. The purpose of the visits was to update the City of Flint (City) 2006 Water Distribution System Sanitary Survey.

In accordance with Section 15 (1) of the Michigan Safe Drinking Water Act, Act 399, P.A. 1976, as amended (Act 399) and the rules promulgated pursuant to Act 399, the City is hereby notified of the need to make water system improvements. Section 15 (1) states: "When considered necessary for protection of the public health, the department shall notify a supplier of water of the need to make changes in operations, to provide treatment, to make structural changes in existing systems, or to add additional capacity as necessary to produce and distribute an adequate quantity of water meeting the state drinking water standards."

Since the 2006 survey, the City has failed to make adequate progress in addressing critical water system improvements. The City is hereby notified to correct the following water system violations.

1. Prepare a water system contingency plan that includes a protocol for placing the stand-by water treatment plant (WTP) into emergency operation.

2. Retain a consultant to perform a water system reliability study. Develop a capital improvements program based upon transmission and distribution system needs revealed in the reliability study and implement asset management principles.

3. Improve distribution system operation and maintenance.

   A. Promote operator certification and training for distribution system operators.

B. Address booster pumping station deficiencies and prepare a schedule.

C. Develop and implement a water system valve program.

Given the number of water system deficiencies that remain un-resolved, the City's water distribution system has declined to a **"Deficient"** rating. Until significant progress is made, the distribution system rating will not improve. Also, for a more thorough discussion of the City's updated survey, please reference the Conclusions and Recommendations section of the 2008 Water Distribution System Sanitary Survey.

Finally, Mr. Robert Misekow is no longer with the City. This leaves the City of Flint without an F-1 certified operator-in-charge (OIC) to oversee operation and maintenance activities at the stand-by WTP as required in Administrative Rule 325.11905 (1), of the Michigan Safe Drinking Water Act (Act 399).

Since no other WTP operators have obtained the F-1 license, the City will need to retain another OIC holding an F-1 license. As a minimum, the OIC needs to maintain an active role in various WTP operations listed below:

- WTP test runs
- Emergency operation
- Continuing education and operator training

We would like to meet with the City to discuss the development of a schedule that addresses the items from the survey and the requirement to obtain an F-1 certified operator. Please contact me at your earliest convenience to arrange a meeting.

If you have any questions regarding these issues or any other water related matter, please feel free to call me at the number listed below.

Sincerely,

Michael F. Prysby, P.E., District Engineer
Water Bureau
Field Operations Section

Water Plant Supervisor

To: Mike Prysby PE.
District Engineer MDEQ

February 27, 2008

From: Brent Wright
Water Plant Supervisor

Subject: Plant effluent to 3mg well

Mike per are conversation the 48" gate valve from plant effluent to the 3mg well is damaged and inoperable. The city has hired Rowe Engineering to redesign the piping through the clear well under the office area at the plant. This clear well in the past was used for backwash water. The well is not needed any more so the piping from the filters to the effluent line will be connected and bypassing the clear well. The design and cost should be in my office the week of march 3rd. I will keep you up to date as the project moves forward.

STEVEN E. CHESTER
DIRECTOR

January 4, 2008

Mr. Robert Misekow, Utilities Director
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

Dear Mr. Misekow:

SUBJECT: 72-inch Transmission Main Emergency

This letter confirms completion of an emergency repair of the 72-inch transmission main in December of 2007. The emergency repair began on December 18, 2007. The repair involved complete replacement of two 20-foot sections of transmission piping due to a significant leak in the pipe joint. Emergency procedures were concluded on December 23, 2006 following completion of the repair and confirmation of no bacteriological contamination within the Flint water distribution system.

We would like to commend the city of Flint for their role in coordinating the remedial activities that minimized interruption in water service. The effort put forth minimized potential impacts to water quality and played a key role in protecting the public health of residents of Flint.

As we discussed, the city will need to file a written report (90-day report) with our office detailing the discovery, cause, remedial measures taken to meet the emergency, and the procedures by which customers were notified. The report also needs to outline the extent of the emergency, its duration, and alternate sources of water supplied during the emergency. The shutdown of the 72-inch transmission main was a real-time event that helped to determine the ability of the city to execute emergency procedures as a means to maintain adequate water service. The report should be prepared in a manner such that it can be used as a reference to assist the city in the event of a similar emergency in the future. Please provide our office with a copy of the 90-day report by no later than April 15, 2008.

Finally, Flint's stand-by water treatment plant was unable to provide an emergency supply of water to the city due an inoperable valve in the plant discharge piping between the treatment plant and Pump Station 4. This valve must be repaired or replaced as soon as possible. Please confirm with us, in writing, as to how this problem will be corrected by no later than January 21, 2008. We would also like to discuss additional chlorination capabilities at the water treatment plant.

If you have any questions regarding this issue or any other water related matter, feel free to call me at the number provided below.

Sincerely,

Michael F. Prysby, P.E., District Engineer
Lansing District Office
Field Operations Section
Water Bureau

STEVEN E. CHESTER
DIRECTOR

July 16, 2007

Mr. Robert Misekow, Utilities Director
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

Dear Mr. Misekow:

SUBJECT: City of Flint, Water Treatment Plant

This letter confirms my visit with Mr. Brent Wright and you on July 3, 2007, at the Flint Water Treatment Plant (WTP). The purpose of the visit was to discuss security provisions on plant grounds, preparing a WTP test-run protocol, and reviewing process monitoring during the treatment plant test-runs. The status of the 72-inch transmission main leak was also discussed. Finally, additional information needed in order to complete the WTP Sanitary Survey and the 2007 Needs Survey was discussed. These items are discussed in more detail below.

The recent fire at WTP No. 1 caused by repeated vandalism raises the issue of security provisions on plant grounds. In spite of a security fence surrounding the WTP site, vandals have been able to gain access to plant grounds. The ability of vandals to gain access to plant grounds increases the vulnerability of WTP No. 2, Pump Station No. 4, Control Station No. 2, and other vital water system structures. Additional security measures including installation of motion sensors and/or intrusion alarms at Pump Station No. 4 and Control Station No. 2 appear necessary in order to enhance security at these locations.

The possibility of razing WTP No. 1 was also discussed as a means to reduce vandalism at this location. We concur with the idea of razing WTP No. 1 since the structure, in its current condition, has been an attraction for vandals. Finally, security cameras have been purchased for the dams along the Flint River and both ground storage reservoirs; however, the cameras are not connected to the WTP's Supervisory Control and Data Acquisition system and are not operational. These security cameras need to be placed into operation.

Next, the next WTP test-run has been scheduled for the week of July 16, 2007. We have also received a WTP test-run proposal that outlines the proposed operation. The proposal was reviewed and our comments were sent to you and Mr. Wright on July 11, 2007. A copy of our comments is also enclosed with this letter.

Next, process monitoring was reviewed. As we discussed, ozone residuals need to be monitored at all three monitoring points along the ozone contactor basin in order to

determine the amount of concentration x time (CT) credit achieved during ozone treatment. Next, chlorine demand and breakpoint chlorination tests need to continue such that additional operating nomographs representing chlorine dosages for varying operating conditions can be prepared. It is vitally important that sufficient CT be achieved in order to ensure that water being sent to the distribution system meets the surface water treatment requirements. Finally, staff needs to continue performing jar tests to determine coagulant feed rates under different operating conditions. Operating nomographs should also be prepared for the other chemical feed applications.

Next, the utilities department has placed a purchase order with a contractor for investigation and possible repair of another leak occurring from the 72-inch transmission main. The leak is located in the vicinity of the Potter and Gale Road intersection. It appears that the investigation and any necessary repair will be delayed until this fall after water usage decreases. We are in concurrence with delaying this work until this coming fall.

Finally, additional information pertaining to the WTP Sanitary Survey and the 2007 Infrastructure Needs Survey has been completed and sent to our office. This information will be used towards finalizing each of these documents.

If you have any questions regarding this issue or any other water related matter, feel free to call me at the number provided below.

Sincerely,

Michael Prysby

NOTICE LETTER
WSSN: 2310

Dear Ms. Cook:

SUBJECT: Stand-by Water Treatment Plant (WTP), Ozone Facility

It has recently been brought to our attention that the Flint stand-by Water Treatment Plant (WTP) no longer has full operating capability. Specifically, the WTP ozone treatment process is not in service due to a computer software problem that is preventing the ozone generators from functioning. The software problem was first identified in March 2007, but for whatever reason, has not been corrected.

Section 325.1015 (2) of the Michigan Safe Drinking Water Act, Act 399. PA 1976 states; *"If upon inspection the department determines that the waterworks system to be inadequate or so operated as to not adequately protect the public health, the department may order the supplier of water to make alterations in the waterworks system or its method of operation as may be required or considered advisable by the department to assure the public supply is adequate, healthful, and in conformance with state drinking water standards."*

The purpose of this letter is to notify the City of Flint of the inability for their stand-by WTP to operate as designed as an emergency stand-by facility due to the lack of ozonation. The loss of ozone as a pretreatment step compromises the WTP's ability to provide potable drinking water in the event of an outage from Detroit. This situation further prohibits the staff of the WTP from conducting comprehensive test-runs to allow operators to effectively operate the plant and produce water meeting the state drinking water standards.

The city is directed to correct the ozone equipment problem as soon as possible.

If you have any questions regarding these issues or any other drinking water related matter, please feel free to call me at the number listed below.

Sincerely,

Michael F. Prysby, P.E., District Engineer

Dear Ms. Cook:

SUBJECT: Water System Reliability
City of Flint – Genesee County

Over the last few years staff of the Michigan Department of Environmental Quality (DEQ) has had several discussions and correspondence with various officials of both the City of Flint (City) and Genesee County (County) regarding water system reliability. The primary issue is the inability to readily supply water from the City's newly rehabilitated water treatment plant to the County's water system.

In April of 1998, the City submitted a Project Plan to the DEQ requesting consideration under the Drinking Water Revolving Fund (DWRF) program for funding to rehabilitate the City's existing standby water treatment plant (WTP). The Project Plan makes several statements indicating that rehabilitation of the WTP was necessary in order to provide a reliable second source of potable water for Flint and Genesee County.

The Summary of Project Need contained within the Project Plan contains the following statement: "Substantial plant upgrades are necessary to meet long-term reliability and water quality requirements as per U.S. EPA and MDEQ Safe Drinking Water Standards. A reliable second source of water continues to be a grave concern to the City of Flint, Genesee County and the Michigan Department of Environmental Quality (MDEQ)."

The Project Background section also states: "Based on our evaluation we conclude that the existing Flint water treatment plant should be rehabilitated to a Phase I firm capacity of 36 MGD, treating Flint River water for an extended period of time (months if needed) to provide the uninterruptible water supply as a reliable back-up to meet the Flint City water needs when the DWSD single pipeline to Flint City/Genesee County fails."

Finally, the City's cover letter that accompanied the Project Plan, signed by then City Administrator David Ready, states: "We are committed to providing the appropriate reliability incumbent upon all water supply utilities should the single transmission main

from DWSD fail." Approval for funding through the DWRF program was granted to Flint based upon the project need and with the understanding that reliability would also be provided to Genesee County. The rehabilitation project was complete as of June 2006.

As far back as September 2004, Genesee County sought to formalize the standby service arrangements, and they proposed a water supply mutual aid agreement. Furthermore, since that time, Genesee County has made several additional requests to meet and negotiate emergency water service from the City with no response. Enclosed is a chronology of the overtures by the County regarding stand-by water service.

Based on this information, the City of Flint has not met a major component of their DWRF Project Plan, and they have reneged on their commitment to provide the appropriate water system reliability.

Water utility officials from both the City and the County have concluded that additional infrastructure (a booster station and some transmission main) is likely needed to readily provide water to the County system. The County has made numerous good faith efforts to begin discussions on how to address these needs plus develop a contract for service. It is time for the City to sit down with the County and move forward on this important public health issue.

Failure to address this reliability issue, and meet the objectives of your original Project Plan may jeopardize approval of any future DWRF proposals.

If you have any questions regarding these issues or any other water related matter, please contact me immediately.

Sincerely,

Michael F. Prysby, P.E., District Engineer

Negotiations for Stand-by Water Source Flint – Genesee County Chronology

Prepared by: Michael F. Prysby, P.E.
March 21, 2007

9/14/04 - Genesee County proposes an Emergency Water Supply Mutual Aid Agreement that contains the following: provisions for an emergency interconnect, a commitment to cover construction costs, and emergency use provisions.

3/30/05 - Genesee County sends a letter to Flint expressing their interest to meet and negotiate stand-by water service.

8/18/05 - Genesee County updates the MDEQ on the progress of various options for stand-by water service. The county states that stand-by water service from Flint is the most desirable option however, there has been no progress towards reaching any type of agreement.

8/31/05 - Genesee County sends a letter to Flint with a stronger emphasis regarding repeated efforts to meet with the city to negotiate stand-by water service. The city is encouraged to open the door for negotiations otherwise the county will have no choice but to pursue other stand-by water service options as required by the MDEQ.

12/9/05 - Genesee County staff meet with interim water treatment plant operator Bill Daniels to discuss building an improved working relationship between Genesee County and Flint. Genesee County also proposes a team approach to assist Flint operators in operating the WTP during an emergency. Genesee County proposes a draft Temporary Operating Agreement in a 12/12/05 follow-up letter.

2/7/06 - Genesee County resends the Temporary Operating Agreement to the city of Flint. Flint's lack of response towards discussing the draft document is also acknowledged in the cover letter.

2/14/06 - MDEQ's comments are sent to Flint regarding the Genesee County's draft Temporary Operating Agreement. The

MDEQ also requested an update on the status of the draft agreement.

9/19/06 - In the wake of the 72-inch transmission main emergency, Genesee County sends another letter to the city of Flint expressing the interest and need to obtain stand-by water service. The letter also enclosed previous letters sent to Flint from Genesee County on this matter.

MDEQ note – according to our records, we have not received any information or feedback from the city of Flint regarding their intentions to negotiate stand-by water service to Genesee County. Also, based upon the information received from Genesee County, the city of Flint has not made an official response to Genesee County on any of their requests to meet and negotiate stand-by water service.

January 30, 2007

Mr. Joe Conroy, Governmental Relations Director
City of Flint
Department of Utilities
1101 South Saginaw
Flint, Michigan 48502

Dear Mr. Conroy:

SUBJECT: Flint Water Treatment Plant (WTP)

We have reviewed your letter of January 5, 2007, informing us of the near completion of the rehabilitation plan for the WTP agreed to by the city of Flint (City) and the Department of Environmental Quality (DEQ) in August of 1999, and as amended in May of 2003.

In your letter, you also inquire as to our support for a project to finish the necessary upgrades to the WTP to allow for continuous operation beyond the plant's present status as an emergency or standby facility. As we discussed in our phone conversation, it is not the DEQ's position to support a proposal or project, but to ensure that the appropriate environmental and public health regulations are complied with and any required permits are obtained.

There are several very important considerations that must be adequately addressed for DEQ to approve the continuous use of the Flint River as the City's source for public water supply, and to issue construction permit(s) for additional WTP equipment and facilities. The major issues are as follows:

- The City will need to submit a complete description of the Flint River as source of supply. Specifically, hydrological data, safe yield, description of the watershed with a discussion of the sources of potential contamination, and a summary of raw water quality. Ultimately a source water protection plan will also need to be prepared.

  It is acknowledged that the City previously used the Flint River as a source; however, switching from purchased water from Detroit is a step back in source water quality. The City will need to address the perception of lower water quality directly if it expects the water customers and citizens to support the project.

date negotiations between the City and the County have not resulted in an agreement for standby service. In addition, there is also some infrastructure (pump station and transmission piping) needed for the WTP to be able to serve the County. These issues need to be addressed as soon as possible so the County also has an emergency source of drinking water.

It should also be noted that a project plan for phase two of the WTP rehabilitation will need to be a comprehensive planning document. Restoring the WTP to continuous service is a significant undertaking and an environmental impact study or at least an assessment may be required as part of a project plan

- Other impacts. A return to continuous service of the WTP will mean contractual issues with Detroit Water and Sewerage Department (DWSD). In addition, as the supplier of Detroit water to Genesee County there are also contractual or political issues there as well. Would Genesee County continue to receive Detroit water from the City or would the County become a direct customer of DWSD? Would DWSD become an emergency source for the City? These issues and questions should be addressed as the part of the City's evaluation of returning the WTP to continuous service.

If the City decides to move ahead with the phase two project, it will be critical for the City and the DEQ to communicate well. Please contact me when you have additional questions. If you have specific Drinking Water Revolving Fund program questions, I would recommend that you call Mr. Clifford Heckathorn directly at 517-373-4725.

Dear Mr. Conroy:

SUBJECT: Flint Water Treatment Plant (WTP)

We have reviewed your letter of January 5, 2007, informing us of the near completion of the rehabilitation plan for the WTP agreed to by the city of Flint (City) and the Department of Environmental Quality (DEQ) in August of 1999, and as amended in May of 2003.

In your letter, you also inquire as to our support for a project to finish the necessary upgrades to the WTP to allow for continuous operation beyond the plant's present status as an emergency or standby facility. As we discussed in our phone conversation, it is not the DEQ's position to support a proposal or project, but to ensure that the appropriate environmental and public health regulations are complied with and any required permits are obtained.

There are several very important considerations that must be adequately addressed for DEQ to approve the continuous use of the Flint River as the City's source for public water supply, and to issue construction permit(s) for additional WTP equipment and facilities. The major issues are as follows:

- The City will need to submit a complete description of the Flint River as source of supply. Specifically, hydrological data, safe yield, description of the watershed with a discussion of the sources of potential contamination, and a summary of raw water quality. Ultimately a source water protection plan will also need to be prepared.

  It is acknowledged that the City previously used the Flint River as a source; however, switching from purchased water from Detroit is a step back in source water quality. The City will need to address the perception of lower water quality directly if it expects the water customers and citizens to support the project.

- Hamilton Dam. The issues regarding this dam have been discussed for a couple years. However, the importance of the dam to WTP operations has yet to be quantified. The dam creates pool depth at the WTP to allow for proper raw water pump operation but the exact operating conditions at the dam and the impact on WTP operations have not been determined. If the dam needs to be removed and replaced, significant costs will be incurred.

  It should also be noted that the dam would not be eligible for funding under the Drinking Water Revolving Fund (DWRF). The DWRF was the funding mechanism for the original rehabilitation plan for the WTP.

- Sludge disposal. If the WTP is returned to continuous operation, provisions for dealing with the residuals of water treatment will need to be addressed. Specifically, ferric sludge from clarification processes, and lime sludge from softening will need to be disposed of properly.

  The two disposal options that have been discussed are: 1) filter press and landfilling or land application, and 2) re-use of the Bray Road Sludge Lagoon. Filter presses are routinely used for this type of waste, but the equipment is fairly expensive and two units would be needed to provide adequate reliability.

  Re-use of the old sludge lagoon poses a number of questions and/or problems. The facility does not meet today's standards for this type of storage facility. In addition, there may have been impacts from previous activities on the groundwater in the vicinity of the lagoon. Therefore, a comprehensive hydro-geological investigation into the site to determine whether groundwater contamination has occurred is needed. If the City wishes to pursue re-use, a complete proposal would need to be submitted that would resolve any contamination that may have occurred, address the fate of the existing solids at the lagoon, and propose a design of any new sludge storage structures including perhaps a surface water or groundwater discharge permit application.

- Drinking Water Revolving Fund. If the City is planning to use this low interest loan program for financing the second phase of WTP rehabilitation, there are a couple of items that need to be addressed. First, the contract for the first phase should be closed out. There are contract issues that should be completed as soon as possible.

  Second, the project to restore the WTP as a standby facility was originally proposed to be able to supply Genesee County Division of Water and Waste Services (County) with a back-up source of drinking water as well. However, to date negotiations between the City and the County have not resulted in an agreement for standby service. In addition, there is also some infrastructure (pump station and transmission piping) needed for the WTP to be able to serve the County. These issues need to be addressed as soon as possible so the County also has an emergency source of drinking water.

It should also be noted that a project plan for phase two of the WTP rehabilitation will need to be a comprehensive planning document. Restoring the WTP to continuous service is a significant undertaking and an environmental impact study or at least an assessment may be required as part of a project plan

If the City decides to move ahead with the phase two project, it will be critical for the City and the DEQ to communicate well. Please contact me when you have additional questions. If you have specific Drinking Water Revolving Fund program questions, I would recommend that you call Mr. Clifford Heckathorn directly at 517-373-4725.

Dear Mr. Benton:

As you know, the City of Flint is nearly complete with its Phase I, Segment IV of the Water Plant rehabilitation plan as agreed upon with the State of Michigan, DEQ in August, 1999.

While the current Water Plant and Facilities can produce water for the short-term duration on a test run basis it is our desire to produce clean, safe water on an on-going basis, if needed. It would be appropriate for the City of Flint to complete the Water Plant rehabilitation to allow the City to be able to produce the projected capacity of 36 million gallons per day in the future. This would allow us more options for the City to decide how they will proceed in the future.

Please confirm your support for the final rehabilitation of the Flint Water Plant to us. (X)

Sincerely,

Joe Conroy

Re: Sanitary Survey Update 2006
DEQ Letter April 14, 2006
Conclusions and Recommendations Response

Dear Mr. Presby:

Water System Viability. The present supervisor holds an S-1 Certificate.

Water Distribution. The program for operator certification remains the same as before.

Water Treatment Plant. Robert Misekow has F-1 Certification. We have encouraged both Brent Wright and Mike Glasgow to write for operator certification this coming year. It is difficult for plant employees to obtain the necessary experience points to qualify for higher certification. It is my belief that restrictions applied to backup waterplants should be relaxed. Our laboratory director, Michael Glasgow, is an ideal candidate for a plant supervisory position, but is hindered by minimal points awarded for four (4) weeks per year of plant experience.

As you are aware Mr. William Daniels has been reassigned to Maintenance Supervisor. I'm unsure if Mr. Brent Wright possesses all of the qualifications required to take the F-1 exam this coming year.

Utilities/Cross Connection Division. Mr. Glen Thomas remains in responsible control of the Cross Control Program. He has submitted his 2005 annual report.

System Storage. Discussions on conditions of the facilities have been held. Scheduling inspections will be addressed Spring of 2007.

Elevated Tank. A requisition was submitted just recently for inspection of the tank.

Pumping Stations. The supervisor at the Water Treatment Plant was told this week to write a requisition for replacement of electrical switchgear and controls at the Cedar Street Station.

Transmission Distribution.

- Pierson Road – two (2) miles of transmission main from Highway 475 west.
- Third Avenue plans are complete. From Third Avenue to Saginaw Street, water mains 4" to 24", ductile iron, estimated at $4,116,000.00 to be completed by October 31, 2007.

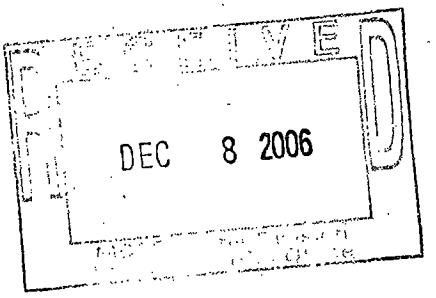
Valve Program. Supervisor making plans for upcoming year.

Contingency Plan. This plan is covered in the previously submitted 90 day report on the 72" Transmission Main break.

Closing. We will respond to the conclusions and recommendations in your earlier letter after reviewing same.

Although we have not addressed all of the items in your Report Summary, it is our opinion that substantial progress has been achieved. All of our supervisors have been made aware of these deficiencies and the next report should see more improvement.

Sincerely,



Robert Misekow

Re: Fire Hydrant Program

Dear Mr. Benton:

As of this week, the Water Service Center has serviced 5,200 fire hydrants. This included flow and drainage checks.

Thirty five are out of service. We expect these to be finished at the end of the month, if line breaks, etc. are not excessive.

We know that the Hydrant Program was high on your list of items to be completed by the City. Our Water Service Center has succeeded in accomplishing a major task, our next job will focus on water distribution valves.

Sincerely,

Robert Misekow

RECEIVED
NOV 16 2006

MEMORANDUM

#2310

TO: Mr. Timothy Benton, District Supervisor
MDEQ

FROM: Robert Misekow
Utilities Director

DATE: November 8, 2006

SUBJECT: Genesee County's 60" Sanitary Sewer Crossing(s)
The City's Water 72" at Kearsley Golf Course Concerns

There appears to be some concern amongst the engineers here that tunneling under the 72" Detroit Water line places us in a compromising position. Perhaps the memory of the City's 72" water transmission repair in August is still fresh in our minds.

It is in the interest of the owner, the county and of course the state, that all possible problems that may be encountered on this job be examined by all parties and that job commencement not be initiated until this is done. We believe that such an integral approach is the responsibility of the county, the state and any contractors that might be involved.

A meeting(s) of all concerned, prior to commencing this project, to discuss mutual concerns relating to maintaining the integrity of the 72" is dictated.

I would like to hear of your experiences in like situations.

Thank you.

Robert Misekow
Utilities Director

Mr. John O'Brien, Director
Genesee County Drain Commissioner
G-4610 Beecher Road
Flint, Michigan 48532

Dear Mr. Misekow & Mr. O'Brien:

SUBJECT: 72-inch Transmission Main Emergency

This letter confirms our meeting on September 7, 2006 at the Flint Water Treatment Plant. Mr. Timothy Benton from our office also attended the meeting. The purpose of the meeting was to discuss the events that occurred during the 72-inch transmission main emergency. The emergency began on August 12, 2006 upon discovery of a leaking valve just west of M-15. The emergency concluded on August 24, 2006 following completion of the repair and confirmation of no bacteriological contamination within the Flint or Genesee County Water service area.

We would like to commend both the city of Flint and Genesee County for their roles in coordinating the remedial activities that minimized interruption in water service. The effort put forth minimized potential impacts to water quality and played a key role in protecting the public health of residents of Flint and Genesee County.

As we discussed, both utilities will need to file a written report (90-day report) with our office detailing the discovery, cause, remedial measures taken to meet the emergency, and the procedures by which customers were notified. The report also needs to outline the extent of the emergency, its duration, and alternate sources of water supplied during the emergency. The shutdown of the 72-inch transmission main was a real-time event that helped to determine the ability of the city and the county to execute emergency procedures as a means to maintain adequate water service. The report should be prepared in a manner such that it can be used as a reference to assist both utilities in the event of a similar emergency in the future. Please provide our office with a copy of the 90-day report by no later than December 15, 2006.

Finally, it would be worthwhile for both utilities to review and update their water system contingency plans relative to mitigating a 72-inch transmission main emergency. Several scenarios were discussed during our meeting and were included in the outline provided at the meeting. Each utility's role, remedial actions, etc. as outlined in the 90-day report can be incorporated into preparing a contingency plan for each type of transmission main emergency.

If you have any questions regarding this issue or any other water related matter, feel free to call me at the number provided below.

Ms. Peggy Cook, City Administrator
City of Flint Water Plant
4500 North Dort Highway
Flint, Michigan 48505

WSSN: 2310

Dear Ms. Cook:

SUBJECT: City of Flint Water System
2006 Sanitary Survey Update

This letter confirms my visits on February 23, 2006 and March 3, 2006 with Bill Daniels, and Michael Brown. The purpose of the visit was to update the city's water system 2004 Sanitary Survey.

The city has addressed certain water-related concerns including; cross connection control and completion of Phase I of the water treatment rehabilitation project. Additional administrative steps are being taken which should set the stage for transmission/distribution system and pumping station improvements during 2006 and 2007.

However, there remain many water system deficiencies of varying concern that have not been adequately addressed, thus, the City of Flint's water distribution system continues to be rated **"Marginal"**. Until significant progress in the major areas (summarized below) is made, the distribution system rating will not improve.

1. Obtain an F-1 certified operator for the water treatment plant and continue to promote operator certification and training for distribution system operators.

2. Develop and implement a water system valve program.

3. Revise the water system Contingency Plan that includes a protocol for placing the treatment plant into emergency operation.

4. Address booster pumping station deficiencies and prepare a schedule.

5. Develop a capital improvements program that addresses both transmission and distribution system needs.

For a more thorough discussion of our updated survey, please reference the attached Conclusions and Recommendations document.

If you have any questions regarding these issues or any other water related matter, please feel free to call me at the number listed below.

Sincerely,

Michael F. Prysby, P.E., District Engineer

Operator Comments

The City of Flint water distribution system is operated and maintained by the Utilities Department. The Utilities dept is broken down into five operating divisions or cost centers out of which three play a key role in operating and maintaining the water distribution system. These divisions are; The Water Service Center, the Water Treatment Plant and the Utilities/Cross Connection Division. Appendix A illustrates the structure and the Utilities Dept and the various cost centers.

The Water Service Center (WSC) is broken down into two divisions, Water Distribution Division (WDD) and Sewer Maintenance Division. The WDD supervised by Michael Brown is responsible for operating and maintaining the water distribution system piping, hydrants, and valves. The WDD also conducts meter reads, replaces meters and maintains distribution system records and maps. This division is broken down into two main branches. One branch focuses primarily on water main operation and maintenance while the other branch is dedicated to meters.

Both branches have numerous operators at various levels of employee responsibility. Appendix B shows and employee organizational chart for the WDD and the certification status among the employees. The water distribution supervisor and the water distribution foreman positions are required to have S1 and S2 licenses respectively. Operator certification, however, is not required nor promoted for the employees assigned to the positions below the distribution foreman level. Several operators at the distribution maintainer level (level 18 maintainer) have acquired the S4 license, however, they were unable to maintain the continuing education credits thus their licenses have fallen to an inactive status. New regulations will eventually require the WDD to have at least two S1 operators.

The water treatment plant (WTP) staff, supervised by William Daniels, operates and maintains Flint's stand-by water plant. Appendix C illustrates the employee organizational chart at the WTP. WTP staff play an important role in distribution system activities and include; operation and maintenance of the city's distribution system pumping stations, storage facilities, and points of connection to other supplies. WTP staff also maintains some of the key programs including both the bacteriological and lead and copper monitoring programs. Finally, WTP staff are responsible for monthly operating reporting, contingency planning and public relations (receipt of customer complaints).

Next, the Utilities/Cross Connection Division, also supervised by William Daniels, is responsible for implementing the City of Flint Cross Connection Control Program. The division has one employee, Glen Thomas who is responsible for conducting the routine inspections and maintaining records. A second employee, Yolanda Gray, assists with recordkeeping and reporting. The division is working towards dedicating at least one and possibly two additional operators towards cross connection control. Any prospective operators assigned to this program are required to be certified master plumbers and must be familiar with cross connection control.

Construction Permit History:

Below is a listing of projects that were completed to improve the reliability of the distribution system pumping facilities, distribution piping, and stand-by treatment facilities.

CP Number	Date	Project	Description
W891667	1/2/1989	Revisions to P.S. 4	Cl Facilites at P.S. 4
W920796	8/12/1992	Dechlorination System	SO2 feed system to de-cl2 filter effluent and backwash water to Flint River.
W931368	11/30/1993	P.S. 4 Improvements	Two 20 MGD high service pumps, one 6 MGD high service pump, valving, appurtenances, etc.
W941607	12/1/1994	Westside Reservoir	Replacement of roofing system, masonry restoration and repairs to expansion joints.
W941678	12/20/1994	C.S. 3 & Dort. Reservoir Inlet	Installation of PRV's at Dort Reservoir and C.S. 3.
W991021	3/23/1999	Cedar St. P.S. Vavle Repl.	Replacement of pump control valves and installation of butterfly valves for each pump.
W991027 W991208	3/10/1999 6/21/1999	GM Transmission Main Repl.	Replacement of 24" trans. Main at GM to serve expansion of facility
W991111	6/23/1999	WTP Rehab Ph I, Seg 1	WTP Rehab, incl. rapid mix, flocc. Basins SCADA contr. And boiler building.
W001136	6/22/2000	WTP Rehab Ph I, Seg 2	WTP rehab, incl. primary clarifier, sanitary sewer connections.
W011130	6/21/2001	WTP Rehab Ph I, Seg 3	Softening, 12 filters, chem feed, O3, residuals mgt.
W041019	2/24/2004	Beech and Wellington St. WM Replacement	
W041082	6/1/2004	Pierson Rd WM Replacement	

The city implemented a plan review/approval process for new watermain extensions and the plan has been in effect for several years.

Comments:

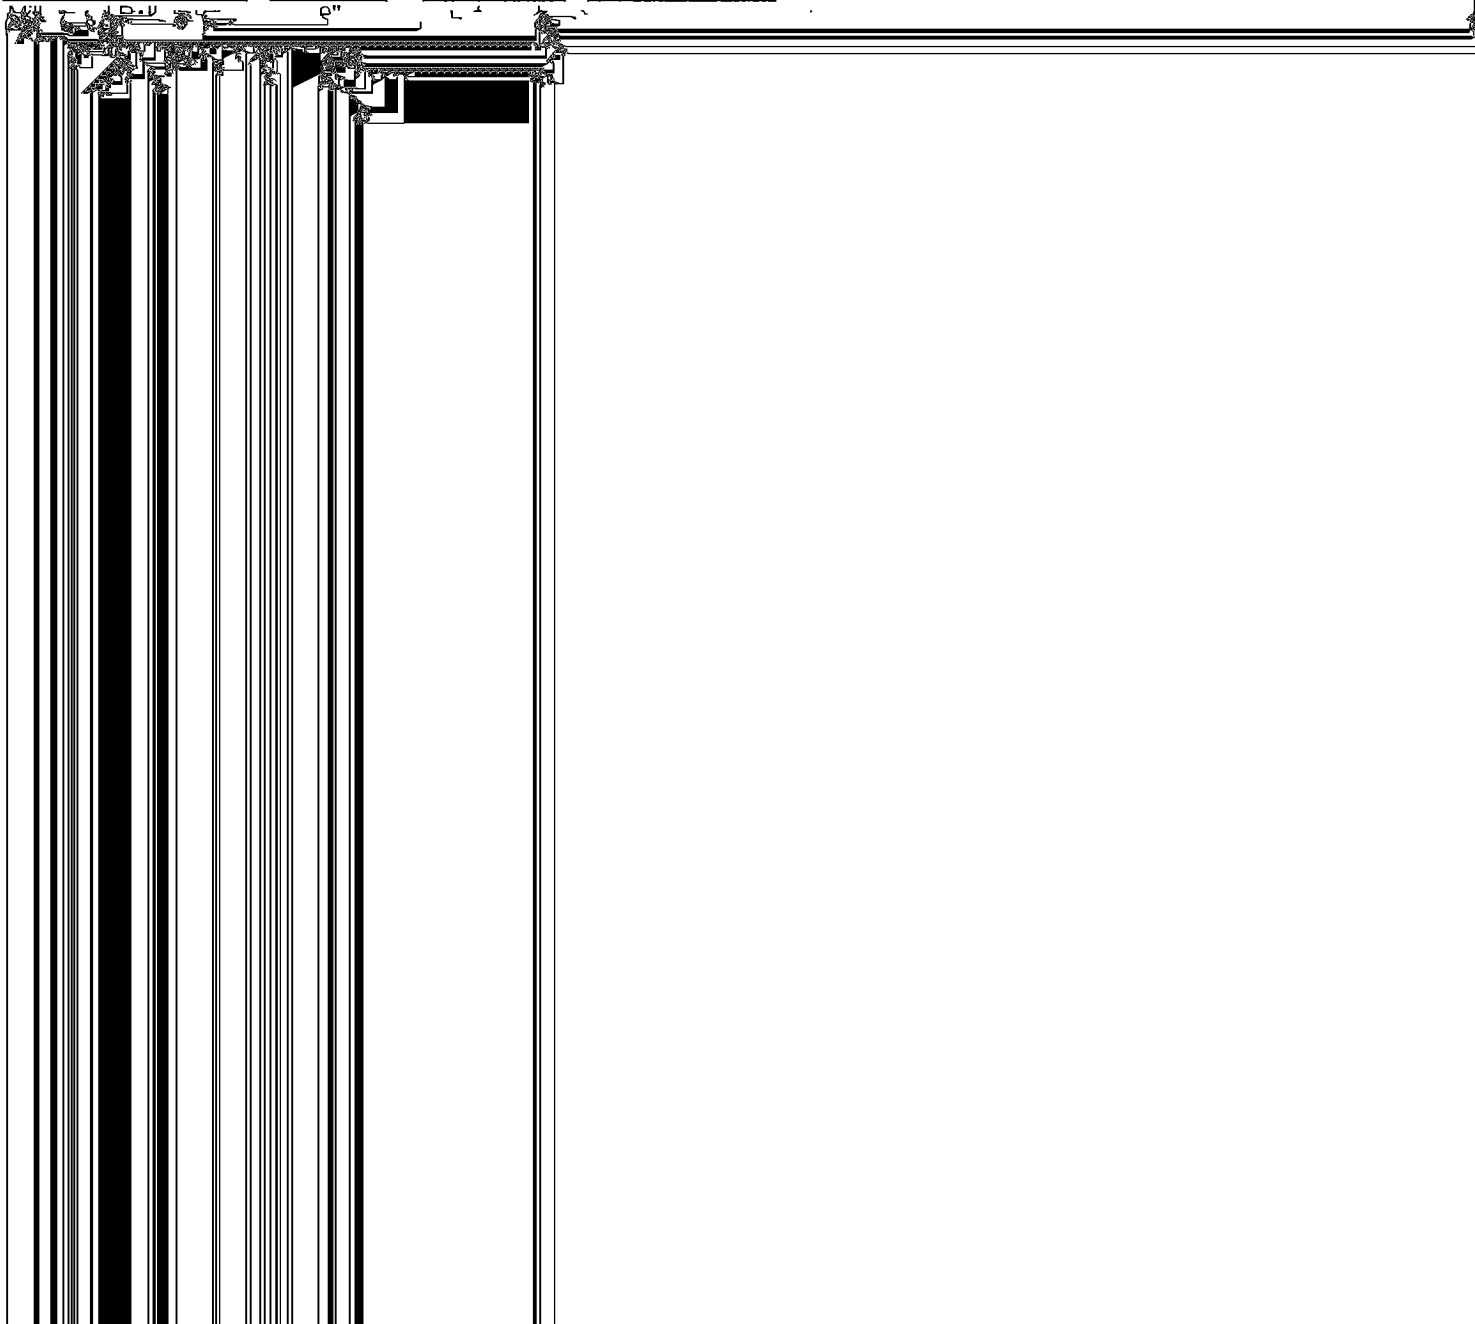
Storage Facility Comments:

Dort:
The Dort reservoir is filled via control station #3. The main to CS 3 tees off the 72"ϕ main upstream of CS 2. WTP staff drained and inspected the reservoir in 1992 and found it to be in good condition. The vent structures above the reservoir are screened and in good condition. These structures are checked and maintained as needed (usually once a year).

#3
WTP staff drained and inspected the reservoir in 1996 and found it to be in good condition. One of the sluice Gates needed to be repaired and was completed at that time. The reservoir is equipped with an internal overflow weir and drain at an elevation of 720'. Security locks are not provided for the access hatches.

Cedar:
The cone valve in the 24" transmission main to the Cedar Street reservoir was repaired following our 2000 evaluation. WTP staff inspected the two-celled reservoir in 1997 and found it to be in very good condition. Cracking and spalling of the concrete walls was minimal. There was a very small amount of sedimentation. The baffle walls were composed of ceramic block and were in good condition.

West Side:
WTP staff inspected the reservoir in 2003 in conjunction with the roof restoration project (CP #W941607). The restoration project eliminated damage to the exterior portions of the reservoir's roof. The inspection did not reveal any build up of sediment, and the reservoir appeared to be in good condition. The reservoir's roof is no longer exposed and the problems associated with stratification of the water within the reservoir during hot weather have been minimized. The improvement allows West Side to be operated on a more continuous pumping schedule. The roof drains along the north side of the reservoir have been repaired and allow adequate drainage of the roof. The high and low alarms at both Cedar and West side are wired such that an alarm situation will either activate or shut down a pump depending of the condition.



Ele. Tank:
Pressure downstream from CS #2 to the elevated tank is throttled such that the operating range of the tank is within its upper portion. The tank basically floats on the system. An interior inspection was performed in 1996 and the tank was found to be in relatively good condition. The tank's exterior was recoated at that time. Since 2000, the tank's controls were upgraded and the cathodic protection system was maintained.

DISTRIBUTION

Interconnections with Other Supplies

Is water purchased from other supplies? (Y/N)	yes
If yes, list WSSN number (s):	DWSD
No. of Emergency Connections:	

Location	Main Size	Est. Capacity	Metered?

Distribution Piping

Identify distribution piping materials - estimate percentages:

Cast Iron	na %
Ductile Iron	na %
PVC	na %
AC	na %
HDPE	na %
Galvanized	na %
Concrete	na %

Estimated percent of piping with coal tar lining Not encountered %

The majority of Flint's distribution system consists of cast-iron and ductile iron piping up to 24" main sizes. The Percentage of CI and DI main is not known at this time. The majority of the larger transmission mains (>24") consists of steel piping.

Identify distribution pipe sizes - estimate percentages:

2"	0.2 %
4"	3.4 %
6"	50.9 %
8"	23.6 %
10"	0.4 %
12"	8.3 %
16"	1.3 %
18"	2.1 %
24"	4 %
30"	0.5 %
36"	0.4 %
42"	0.1 %
48"	0.1 %

The city has replaced watermain since 2000, however, the overall shift in percentages is less than 1% in all catagories.

Avg Day Demand @ this location 1 mgd

Firm Pump Capacity/Max Day _____ %

Peak Hour/Firm Pumping Capacity _____ % (Hydropneumatic Stations)

Aux. Power Capacity/Avg Day _____ %

Comments:

A detailed pump inspection including a pump efficiency test has not been performed within the past five years.

Daily pumpage is estimated and is recorded on the daily sheets.

The Cedar Street pumping station consists of three single stage horizontal centrifugal pumps that takes suction from an adjacent 20 mg reservoir during peak demand periods. The reservoir is re-filled during low demand periods. Pump operation and filling of the reservoir can be controlled at the WTP or manually at the booster station. Pump operation setpoints are located within the distribution system.

The average day demand through this station is determined by the amount of water taken from the storage reservoir. The station operates on a pump and fill cycle and alternates with the westside pump station on an every other day basis. This station is capable of metering total pumpage on a daily basis. The pump status is relayed via the SCADA system to the operations center.

The electrical controls and switchgear, late 40's vintage, remain outdated and most of the replacement parts are no longer available. A complete rehabilitation of the electrical system is still needed at Cedar Street. Also

the building roof is in need of replacement. Soft-starts for each pump may also be included with the improvements. These improvements are planned in Flint's 2006 annual budget.

Pump maintenance consisting of lubrication and inspection is conducted once a month on all pumps at all of the booster pumping stations. Each pump is operated at least once a month.

Two of the existing cone valves were replaced with 14" pump control valves for pumps 2 and 3. Butterfly valves were also installed on the discharge side of all three pumps. Pump 1 is still controlled by the existing cone valve, however, the vavle has performed satisfactorily.

The gas chlorination system was removed and replaced with the ability to feed sodium hypochlorite. Three chlorine feed pumps are available at the pumping station. A new chlorine residual analyzer was installed and the information is relayed to the operations center.

The pump station is well maintained and the housekeeping is above average.

Westside Pumping Station (P.S. No. 5)

Location: Westside
Function: Provide supply from an adjacent 12 mg reservoir during peak demand.

Avg Day Demand @ this location 1 mgd

Firm Pump Capacity/Max Day _____ %

Peak Hour/Firm Pumping Capacity _____ % (Hydropneumatic Stations)

Aux. Power Capacity/Avg Day _____ %

Comments:

A detailed pump inspection including a pump efficiency test has not been performed within the past five years.

Daily pumpage is not metered at Westside.

The Westside pumping station consistes of two three stage turbine pumps and two two stage turbine pumps that take suction from an adjacent 12 mg reservoir during peak demand periods. The reservoir is re-filled during low demand periods during the winter months. During the summer months the station operates on a continuous pump and fill cycle and the operation alternates every other day with the Cedar Street station. Pump operation and filling of the reservoir can be controlled at the WTP or manually at the booster station. Pump operation setpoints are located within the distribution system.

Flow is measured by the elevatioin changes in the reservoir along with the pumping duration of the operating pumps within the facility. Direct metering to record daily demands is not provided at West Side.

Modifications to the pump-discharge valving is needed. The existing 4 mgd pumps are equipped with swing check valves. This design causes rapid valve operation during pump start-up and bumps the distribution piping downstream and most likely contributes to the main breaks in this area. The larger pumps are equipped with cone control valves, however these are not functional. One butterfly control valve is out of service. The other control valve utilizes a hydraulically operated butterfly valve however, these valves have not worked since 1990. The city has budgeted funds for 2006 and 2007 for new pump control valves at West side. Butterfly valves will also be provided for the two larger pumps.

The gas chlorination system was removed and replaced with the ability to feed sodium hypochlorite. Three chlorine feed pumps are available at the pumping station. A new chlorine residual analyzer was installed and the information is relayed to the operations center.

The switchgear has been re-conditioned and the station piping repainted.

Pumping Station No. 4 (P.S. No. 4)

Location: P. S. #4
Function: Provide supply from 20 mg reservoir during peak demand.

Avg Day Demand @ this location _____ mgd

Firm Pump Capacity/Max Day _____ %

Peak Hour/Firm Pumping Capacity _____ % (Hydropneumatic Stations)

Aux. Power Capacity/Avg Day _____ %

Comments:

A detailed pump inspection including a pump efficiency test has not been performed within the past five years.

A stand-by power generator exists but is not capable of providing sufficient power. Dual electrical feeds have been provided for P.S. #4 from two separate substations.

Pump Station #4 was rehabilitated in 1994. Three pumping units were added, two 20 mgd pumps and one 6 mgd pump to improve turn over on the 20 mg Dort reservoir. The project also included installation of a second 42" discharge line. This project increased the firm pumping capability of PS 4 to 60 mgd. Pumps 3-6 are low lift pumps and are not utilized for pumping treated water to the distribution system. Pump 9 is used to continuously turn-over the Dort reservoir.

Torrey Road Pumping Station

Avg Day Demand @ this location _____ mgd

Firm Pump Capacity/Max Day _____ %

Peak Hour/Firm Pumping Capacity _____ % (Hydropneumatic Stations)

Aux. Power Capacity/Avg Day _____ %

Comments:

A detailed pump inspection including a pump efficiency test has not been performed within the past five years.

The Torrey Road station functions an in-line booster pump station and takes suction form a 24" transmission main along Hammerberg Rd. This station boosts pressures in the SW portion of the city. Pump operation is based on a pressure monitor located at Brown St and Brakley Ave.

The larger pump at this station is rarely used due to its high discharge head. A new, smaller pump or a variable frequency drive is needed at this facility for more reliable and efficient operation.

Improvements are planned for the Torry Road station. Several alternatives are being evaluated and include adding to the existing station or construction of a new station. In either alternative, variable frequency drives, replacement of all pumping and electrical equipment, additional pumping capacity, and establishment of an additional pressure district will be provided. The city has included this project in their 2007 budget.

General Comments:

All pumping stations are visited five times a week and sampled twice a week. All of the stations appear well maintained and the housekeeping is above average.

Pump availability, electrical controls, switchgear and stand-by power are important issues that need to be addressed among all four pumping stations. The city needs to follow through with improvements that are budgeted for during 2006 and 2007.

DISTRIBUTION

Operational Concerns & Maintenance

Are there areas where water main breaks are frequent? (Y/N) yes

If yes, identify locations:

Oxley Dr
Susan St
Flemming Rd
Flushing Rd past Milbourn
Dupont St. From Flushing Rd to Dayton
Area SE of Swartz Creek Valley Park
Boulevard Dr near Army Reserve
Janet Dr and Webster Rd
Avril St

Comments: Main breaks also occur in many other areas of the city. It appears that the most frequent breaks occur in the areas listed above.

Are there areas where aesthetic water quality complaints are frequent? (Y/N) no

Comments: In general, water quality complaints are not received. Occasional complaints do occur from unanticipated flushing following street sweeping work and those associated with watermain repairs.

Do you receive complaints alleging illness due to the water? (Y/N) _____

Is a procedure in place to respond to and track these complaints? _____

Comments:

Are there areas where customers complain of low pressure? (Y/N) no

Comments: Recently there hve been no low pressure complaints. Any complaints that are received are usually attributed to failed service or corroded plumbing. Low pressures in the area known as Hospital Hill have been alleviated with the new tie-in along Sunset and discontinuation of the City/Genesee county connecteion at Beecher Rd.

DISTRIBUTION

Operational Concerns & Maintenance

Are there areas where fire flows cannot be maintained? no

Comments: The majority of the city's system has adequate transmission piping to convey sufficient flows and pressures for fire protection.

Last ISO report date? could not be found Rating _____

Which, if any, of the above listed areas has the supply prioritized for main replacement, upgrading, or looping? Also, if a definite schedule for capital improvement has been established, list the proposed completion date.

Previous DWRF project plan proposals identified various distribution and transmission system improvements. These improvements were broken into several phases. The city did not score high enough to qualify for funding, however, these improvements remain as water system needs.

Phase 1: Replace 8200' of 12" main in Flushing Rd from DuPont to Eldorado St.
Replace 1900' of 24" main in DuPont St from Flushing north to Mackin.

Phase 2: Replace 8500' of 24" main in Dupont St from Mackin to Seminole St. This also includes Seminole st, Welch Boulevard, Euclid Ave, Stockdale St Iroquois Ave and Passadena St.
Install 350' of 8" main in Edgemont from Beecher north to VanBuren

Phase 3: Replace 1100' of 16" main in DuPont St from Chevrolet to West 3rd st. Replace 2900' of 12" main in McClellan St. from Iroquois Ave to Fleming Rd.

Phase 4: Replace 7700' of 16" main on Pierson rd from Clio Rd to MLK Jr Ave.

Comments The city received approx. $200,000 from community block grant funds in 2004 and utilized these funds for valve replacement in Pierson Rd and Flint Park Areas. The city did not receive grant funding in 2005.

The city anticipates between $300,000 and $400,000 in community block grants in 2006 and these funds will be used for hydrant and valve replacement. The WDD would like to see all of the 3 and 4" mains be replaced.

New 16" main was installed along Pierson Road thus completing a portion of phase 4 of the suggested water system improvements.

The city is considering to replace watermain in Flushing Rd in 2007 listed in phase 1 of the water system improvements.

It does not appear that the city has a capital improvements plan in place for WM replacement.

DISTRIBUTION

Hydrants

Number of Hydrants	4500	
Number Without Auxiliary Shut-Off Valves	not aware of any	
Number that are Self-Draining	undetermined	*
Number of Inoperable Hydrants	5	**

Frequency of Hydrant inspection: 1/yr (fall)

Inspection Staff: L18 Maintainers L19 Equip. Ops.
Dist. Foreman

Comments:
* All hydrants are ordered plugged, however, a few are unplugged.
** The number of inoperable hydrants is always changing. Hydrants that are found in a state of disrepair are usually repaired within one week.

Are there areas where additional hydrants are needed? some areas

* - Would like to establish a 300-500' hydrant spacing standard.

Hydrant location system yes Accurate? yes

-Records depicting hydrant blueprints and cards are in place and appear to be accurate.

Are hydrants color coded for capacity? yes

- Hydrant caps are coded by main size, but this coding system is not consistant. WDD intends to paint hydrant bonnets according to main size.

Has this information been provided to the fire department yes

-Fair communication with fire dept.

Frequency and seasons of hydrant flushing 1/yr (fall)

-Hydrants are flushed once a year during the fall. Flushing is performed to maintain water quality and upkeep hydrants.

Purpose of flushing aesthetics

Is the public notified prior to flushing? No

Does flushing follow a specific format? somewhat

-Flushing is set-up on a per grid basis with 50-100 hydrants per grid. Usually one operator is assigned to a grid. There is no order in which the grids are flushed.

Is the volume of water used during flushing estimated? no

Is a record maintained of hydrant activities? yes

-Hydrant records and work orders are maintained, however, information from the work order has not been transferred to the hydrant records.

Comments:

Hydrant records consisting of hydrant cards and work orders exist, however, the hydrant cards are not updated to reflect recent repairs and/or maintenanace. This information is maintained separately in the work order records. The Utilities Division will request approval to purchase a data retrieval system (GBA system) in 2006 for use towards improving hydrant and valve recordkeeping. The

public is not informed of system flushing.

An improvement in comunication between the WDD and the fire dept is needed regarding the status of system hydrants. Specifically, 911 emergency service convoys information concerning broken hydrants to the fire dept. Information on recently repaired hydrants is not conveyed to the fire dept.

DISTRIBUTION

Valves

Number of Valves: 8000-10000 MDEQ est

Number of inoperable valves: many

Are there areas where additional valves are needed? yes

If yes, list locations:
Along Saginaw St and many other areas
The WDD indicated that many of the city's valves do not work and has resulted in larger than necessary interruptions in water service to make the necessary repairs.

Valve location system: partial system Accurate? yes

Valve Turning Frequencies: no program in place

Comments:
The reason given for the lack of a valve turning program is an insufficient workforce.
The city has purchased a valve turning trailer. The city is also preparing to bid replacement of two valve trucks.

Records Maintained? < 25% adequate records of distribution system valves.

Comments:

The city's valve program remains deficient. A valve turning program is not in place for either primary and secondary system valves. Many vavles are not in working order. It is estimated that the city has between 8000 and 10000 isolation valves, but there has been little or no improvement in valve records since our 1999 survey. The majority of these cards repreent valves in mains 16" or larger. Although the location, description, and operating details are accurate much of the information has not been updated.
Little additional work has been make in the past 7 years towards re-establishing an adequate valve recordkeeping system.

If the Utilities Division acquires the GBA system, improvement in the valve program should proceed. Staff will be acquired to operate and input data into the GBA system. It appears that additional staff are needed to address the problems in the valve program.

PROGRAM COMPLIANCE

Cross Connection Programs

Ordinance No: 3267 Date: 1/24/1994

Approved Program (Y/N)? yes Date:

Staff Assigned to Program, (No., Dept and/or who) Utilities Administration/Cross Connections

Is Annual Cross Connection report required (Y/N)? yes

Was previous year's annual report received (Y/N)? yes Date Received: 3/26/2005

Was previous year's annual report acceptable (Y/N)? yes

Inspection Status: Rountine inspections have resumed

Device Testing Frequency: 2x/yr (high hazard) 1x/yr (mod. and low hzd)

Recordkeeping: Improving

Private Well Isolation/Abandonment Procedure:

Comments: The Utilities Administration Division along with WTP staff are becoming involved with cross connection inspections. Mr. Glen Thomas is now involved with cross connection inspections and back flow prevention on a full-time basis. William Daniels, WTP superviser, supervises the CCCP.

Annual Pumpage Reports

Is Annual Pumpage Report required (Y/N)? no

Monthly Operator Reports

Are Monthly Operation Reports required (Y/N)? yes

Were all previous year's reports received (Y/N)? yes Timely? yes

Are previous year's reports acceptable (Y/N)? yes

Comments:

Consumer Confidence Reports

Is the annual CCR requires? (Y/N) yes

Was the previous year's report received? (Y/N) yes Timely?

Was the previous year's acceptable? (Y/N) yes

Was the previous year's certification form received? (Y/N) Timely?

Comments: A copy of Flint's CCR and water quality data can be found in appendix D.

PROGRAM COMPLIANCE

Contingency Plan

Date of Most Recent Plan: 8/1/1992 Acceptable? no

Filed where? MDEQ, WTP

Comments:

the WTP's 1992 contingency plan discusses the scenario of either an inadequate amount of water or a failure of the 72" pipeline. The contingency plan does not provide sufficient information concerning critical contacts in the event of an emergency. This would include police, fire, critical customers, contractors, suppliers, etc. Other information that was provided also needs to be updated.

Flint prepared an Emergency Operations Plan (EOP) that outlines action to be followed for: source water and distribution system contamination, man made and natural disasters, and enemy attack emergencies. The EOP does not provide an outline to follow in the event of a failure of the 72" transmission main and a widespread power outage. An addendum to the EOP was to be prepared and would include these additional emergency items. Also, the EOP needs to contain a protocol for placing the WTP into service during an emergency.

The city is planning to provide stand-by power provisions at Baxter and Potter.

WTP staff indicated that repair of the 72" transmission main can be completed, however we have yet to receive a plan that outlines how this type of emergency would be mitigated.

Finally, the contingency plan and/or the EOP needs to be updated to reflect changes in emergency contacts. The revised plan also needs to include a protocol for placing the WTP into service for emergceny operation.

General Plan

Date of Most Recent Plan: 1990 Acceptable? _____

Filed Where? Water Service Center

Comments:

An updated map with 1990 distribution system info is available. The WSC also has a series of individual maps of the distribution system. Finally, the hydraulic model has been completed and contains the entire distribution system.

Reliability Study

Date of Most Recent Study: _____ Acceptable? _____

Filed Where? MDEQ, City

Comments:

The city has several completed reliability studies which discuss the issue of source reliability. The most recent study (DWRF Project Plan by SEG) addresses the issue of source reliability. The project plan also discusses future water usage and distribution system needs. The plan adequately addresses the city's transmission needs, however, much of the city's smaller distribution piping may soon be reaching the end of their service life.

Permits

Applies for and obtains permits prior to construction (Y/N): _____
Reviews plans from engineers and/or developers prior to submittal to DEQ (Y/N): _____
Standard specifications on file at CWS (Y/N): _____
If applicable, adheres to contract with supplier regarding plan submittal (Y/N): _____
Follows master plan for any construction (Y/N): _____
Actually follows plans as permitted (Y/N): _____
Develops as-built plans (Y/N): _____
Updates general plans (Y/N): _____

Capacity Development

Radon	_____	Date Collected _____
Tritium	_____	Date Collected _____
		_____

Detects for Rads > 50% of MCL? (Y/N) _____

If yes, list

Comments:

Conclusions and Recommendations

In general, our survey covers the major aspects of a water supply including: stand-by facilities, distribution, source capacity, and storage. Each of the above categories are evaluated on the basis of adequacy, maintenance, reliability, and operation. The evaluation also includes a check on the status of the operator certification and the cross connection control program. Finally, water quality and the utility's monitoring programs are reviewed.

Overall, the City of Flint's water distribution system continues to be rated **"Marginal"**. Improvements are needed in several key areas including: pumping station improvements, distribution system capital improvements, and in various operational programs. Until significant progress in these major areas is made, the distribution system rating will not improve. Further discussion regarding existing facilities, reliability, operation, and maintenance is provided in more detail below.

Water System Viability

The City of Flint currently serves a population of approximately 125,000 through an extensive network of transmission and distribution mains. Several booster pumping stations and storage facilities are in place to enhance service. A system of this size and complexity must have an adequate number of certified operators to adequately maintain and operate the system.

The Safe Drinking Water Act specifically sets the city's minimum certification requirement to employing at least one S-1 certified operator to oversee the operations of the water utility. The remaining staff at the Water Service Center (WSC) and the Water Treatment Plant (WTP) must also be well qualified to perform water distribution system operation and maintenance in an adequate manner and should hold some level of operator certification.

Water Distribution Division (WDD)

The WDD, supervised by Michael Brown, operates and maintains the water distribution system piping, hydrants and valves. The WDD also conducts meter reads, replaces meters, and maintains distribution system records and maps. The city continues to mandate the S-1 and S-2 certification requirement for the supervisor and foreman positions respectively. Operator certification, however, appears to have declined among the Level 18 Maintainer positions. Several certified operators in this position were unable to obtain their continuing education credits (CECs), thus their licenses have fallen to an inactive status.

Although the WDD meets the minimum operator certification requirement, we encourage the city to promote operator certification in the entry-level positions. Specifically, Distribution Trainees and Maintainers should attain and maintain their S-4 and S-3 certificates respectively. For those who acquire their S-4 or S-3 certificate, CECs must be accrued in order to keep these licenses active. Specifically, these certificates fall into a three-year renewal period during which 1.2 and 2.4 CECs for the S-4 and S-3 respectively must be accrued.

Certified operators help to protect Flint's investment in the drinking water system and to meet the Safe Drinking Water Act's requirements. Other utilities have found it beneficial to institute a bonus incentive program for attaining operator certification. We encourage the city to promote operator certification among all water operator positions. Additional information detailing the requirements for operator certification, available training, exam applications, etc. is enclosed.

Water Treatment Plant (WTP)

The WTP staff, supervised by William Daniels, operates and maintains Flint's stand-by water treatment plant. The WTP staff also maintains certain water utility programs including pipeline operation and the bacteriological and lead/copper monitoring programs. WTP staff are also responsible for monthly operation reporting, contingency planning, and public relations.

However, the city of Flint remains without an operator in charge (OIC) holding the required F-1 license to oversee operation and maintenance activities at the WTP. According to Flint's February 28, 2006 letter from Peggy Cook, City Administrator, there has been no further progress towards negotiating a draft operating agreement with Genesee County. The city has also informed us that a request for proposal to enable engineering firms to provide an interim F-1 operator has been prepared and will be distributed to several consultants. Finally, Mr. Daniels will re-write the F-1 certification exam this spring.

The next F-1 certification exam is on May 3, 2006. In the event that Mr. Daniels does not pass the exam, the city must acquire an interim OIC holding an F-1 certificate by no later than July 1, 2006. Given the time constraints, the city needs to continue negotiating efforts with Genesee County as soon as possible and/or proceed in the selection process of an F-1 contract operator. Finally, even if Mr. Daniels passes the F-1 exam, Genesee County has staff that would provide a significant amount of technical assistance in operating the WTP in the event of an emergency.

Utilities/Cross Connection Division (UCCD) - Cross Connection Control Program

UCCD is responsible for implementing the city's cross connection control program (CCCP). Mr. Glen Thomas continues to perform routine inspections and maintain records. Ms. Yolanda Gray assists with recordkeeping and reporting activities.

The city's CCCP is rated satisfactory in implementation and program administration. Based upon our discussion and review of the 2003 and 2004 annual reports, an adequate number of routine inspections are being completed among Flint's high and low priority establishments. The UCCD has also replaced the local cross connection ordinance (Ordinance No. 3267 with Ordinance No. 46-43.1) The new ordinance is generally acceptable; however, it references various city and state agencies that are outdated. Finally, we have not received Flint's 2005 cross connection annual report.

The UCCD is working towards obtaining an additional operator for CCCP implementation. We encourage the city to review the needs the CCCP with the UCCD and achieve the necessary staffing to meet the annual inspection schedules.

System Storage

Flint has five storage facilities that provide a total storage volume of 57 million gallons (MG). These facilities, based upon our survey and previous inspection records, appear to be in good condition.

Dort Reservoir

The 20 MG Dort reservoir was drained and inspected by the WTP staff in 1992 and found to be in good condition. The exterior structures including vents and overflows are checked and maintained on a yearly basis. The reservoir is due for a re-inspection.

3 MG Reservoir

The 3 MG transfer reservoir upstream of Pump Station #4 was inspected in 1996 and found to be in good condition. Repairs to an existing sluice gate were completed at that time. The reservoir is due for a re-inspection. Provisions for venting and an overflow structure should also be evaluated during the next inspection.

Elevated Tank

The 2.0 MG elevated tank was inspected and repainted both inside and out in 1996. The inspection revealed that the tank was in good condition. The elevated tank is due for a re-inspection.

Westside

The 12 MG reservoir was inspected in 2003 by WTP staff in conjunction with a roof restoration project. As part of the roof restoration project, the roof drain (scuppers) were repaired. The completed work allows for adequate drainage of the roof. The

internal inspection revealed minimal sediment build-up and the reservoir appeared to be in good condition. The reservoir should be re-inspected between 2013 and 2018.

Cedar Street

The 20 MG reservoir was inspected by WTP staff in 1997 and found to be in very good condition. Minor sedimentation was noted and, cracking and spalling of the concrete walls was minimal. Vents and overflow structures were also in good condition as noted in our survey. This facility is due for a re-inspection.

Pumping Stations

The city of Flint has four booster pumping stations. These pumping stations along with various comments and/or concerns are listed below.

Cedar Street Station

The electrical switchgear and controls remain outdated and replacement parts are no longer available. A complete rehabilitation of the electrical system is still needed at Cedar Street. It is our understanding that the city intends to proceed with electrical improvements during FY 06.

Westside Station

Valving modifications on the pump discharge piping are needed. Specifically, the two smaller pumps are equipped with swing check valves. This type of configuration causes rapid valve operation during pump start-up and this condition causes water hammer within the distribution system. This condition has contributed towards some of the main breaks in the area. The two larger pumps are equipped with cone control valves; however, these valves do not function properly. It is our understanding that the city has included new pump control valves for the Westside station in the FY 06 budget.

Pump Station No. 4

This pumping station, located at the WTP, was re-habilitated in 1994. Our inspection revealed that the facility is in good condition. Stand-by power is not provided for this facility; however, dual electrical feeds from separate substations have been provided.

Torrey Road

Improvements are planned for this pump station and are currently being designed. Based upon our discussion, the existing station will be replaced with a new station.

The new pump station will include variable frequency drives and establishment of a new pressure district.

A construction permit will be required prior to proceeding with construction of the new pump station. A set of construction plans, a basis of design for the pump station, and a permit application will need to be sent to our office for review and approval prior to issuance of the construction permit. Finally, any new booster pump station should also include stand-by power.

Tranmission/Distribution

Flint's water system consists of an extensive network of distribution and transmission mains. Our main concern with Flint's distribution system is the condition of the piping. The WDD staff continue to indicate that the majority of the three and 4-inch main in the city is in very poor condition and needs to be replaced. Specific areas in need of replacement are listed in the data-gathering portion of the survey.

Some improvements were completed since 2000 and the upgrades included transmission main replacement along Pierson Road and Beech & Wellington Streets. Next, the city is considering replacing transmission mains in Flushing Road in 2007.

Although the city has replaced some transmission main over the past six years, a high percentage of the distribution piping remains over 60 years old and is in serious need of replacement.

The city needs to establish a capital improvements program (CIP) for watermain replacement. The CIP should reference distribution/transmission improvements that are recommended in the 1999 distribution system study and hydraulic model prepared by the Snell Environmental Group, Inc. The CIP should also coordinate other distribution system improvements with sewer and road replacement projects and be based upon WDD's recommendations.

Valve Program

The WDD is responsible for maintaining and keeping track of distribution system valves; however, this program remains **deficient**.

Listed below (in a decreasing level of importance) are the elements that are essential towards establishing an acceptable valve program:

- Locate valves in critical areas, verify proper operation, and establish adequate records
- Locate remaining valves in less critical areas and establish records

- Institute valve turning program – beginning with critical valves

Next, it is our understanding that the WDD will request approval to purchase a data retrieval system in 2006 for use in improving hydrant and valve records.

It is essential that the city approve the software package that would allow the WDD to establish an adequate recordkeeping system for valves and other distribution system appurtenances. An adequate recordkeeping system is an essential component of the valve program and is vital in allowing WDD operators properly operate and maintain this infrastructure.

Finally, any valve exercising activities should also be included with individual valve records. Although it would not be possible to turn all system valves on a yearly basis, we would suggest that an exercising schedule be established especially for valves in critical locations. This should consist of reviewing all valves and determining what percentage of valves could be exercised each year.

Contingency Plan

The city of Flint needs to prepare an accurate water system contingency plan that reflects potential water system emergencies. Flint's Emergency Operations Plan (EOP) prepared in 2003 contains some of the elements of a water system contingency plan; however, much of the information (emergency contacts) is becoming outdated. In addition, the EOP addresses only a limited number of potential water system emergencies that could confront the city.

The water system contingency plan needs updated to reflect all current emergency contacts. The plan also needs to be expanded to include, but not limited to, the following water system emergencies: failure of the 72-inch transmission main, widespread power outage, large transmission main break, source water and distribution system contamination, critical equipment failures (treatment components, pumping station, storage facilities, etc). Finally, the contingency plan needs to contain a protocol for placing the WTP into service in the event of an interruption in water service from Detroit. Emergency operation of the WTP is a crucial part of the city's water system contingency plan and the plan needs to be updated to include WTP operation under this type of emergency.

Closing

Some of the items in this survey including: operator certification, treatment plant operation, and distribution system improvements were discussed in our most recent correspondence. We are requesting the city to respond to us in writing on each topic discussed in the Conclusions and Recommendations portion of the survey. Following our review of the city's response, we will schedule a meeting to discuss these issues in more detail.

Report Summary

The following is a list of items discussed in this report which must be addressed by the city of Flint. No priority is implied by the order in which the issues are presented. Page references are noted in parentheses.

1. Continue to inspect and maintain the water storage facilities. Improved security should be taken for the facilities at the WTP. (5,6,28,29)

2. Address booster pumping station deficiencies including: electrical upgrades at Cedar Street, pump discharge valving at Westside, stand-by power at each pumping station, and new pumping station at Torrey Road. (9-13,29,30)

3. Develop a capital improvements program that addresses both transmission and distribution system needs. (15,30)

4. Establish an adequate O&M program and recordkeeping system for hydrants and valves. (17,30,31)

5. Revise the water system Contingency Plan. (22,31)

6. Promote operator certification and training. (2,26,27)

Re: F-1 Licensed Operator
Water Plant

Dear Ms. Cook:

On December 9, 2005, David Jansen and I met with Bill Daniels, in his office, to review and discuss an improved working relationship between the two water departments.

In review of the request for an F-1 licensed operator, the County is proposing to offer a team approach to assist Mr. Daniels in operation of the facility. The team would consist of licensed operators, engineers, and a safety officer. While this seems like a lot of personnel, it really is not anymore than offering one person based upon time required to perform the work. The operators would assist Mr. Daniels in start-up and running of the plant. The engineers would assist Mr. Daniels in closing out the construction projects, and the safety officer would assist Mr. Daniels in maintaining the facility in compliance with all current regulations, both Federal and State. At the request of Mr. Daniels, I have prepared a draft agreement as a starting point to our endeavors (enclosed).

The second item we discussed was that of an emergency backup supply plan between the City and County. While it is in its infancy, I have also proposed an agreement for proceeding down this path of cooperation.

The third item discussed was a study by the County for raw water supply. As you know, the County is trying to determine our long-term water supply options. One option considers bringing raw (untreated) Lake Huron water to Genesee County and treating it to drinking water standard. The County personnel believe that this option would also benefit the City of Flint. It is recognized that the City would save money by completing the treatment plant and using Flint River water as its source of water. We believe that using the Flint Treatment Plant and treating raw lake water would increase these savings to the City of Flint through reduced construction costs and reduced operations cost. The County proposes to fund a study to calculate this option; all we are asking of the City is to provide accurate data for the study.

Based upon the above, we believe the following are the next steps:

1. Finalize a temporary operating agreement.
2. Finalize an emergency back-up operating agreement.

3. Authorization to Mr. Daniels to share information for the raw water study.
4. Presentation of the agreements to the Mayor and Drain Commissioner for their consideration.

Knowing the time constraint the City is under, the County staff and I are available at your convenience. Should you have any questions, do not hesitate to contact this office.

Sincerely,

John F. O'Brien, P.E., Director
Division of Water and Waste Services

Draft

Temporary Operating Agreement
between City of Flint Water Department (Flint) and
Genesee County Drain Commissioner's office
Division of Water and Waste Services (County)

The purpose of the temporary operating agreement is for the County to provide a licensed operator for the water treatment plant until such time the City has a permanent operator on staff or under contract. The terms of the agreement are as follows.

1. The County will provide the following services to the City:
   - Provide qualified personnel to assist the plant manager in overseeing the ongoing construction at the City water plant.
   - County will participate in progress meetings.
   - County will observe construction installation.
   - County will review completion records.
   - The County will make all recommendations and comments to the contractor through the City of Flint.

   Product: The County will prepare quarterly reports, which will contain the status of the project, for the City Mayor's office.

2. The County will monitor test runs of the water treatment plant. The County will observe all test runs of the facility and make recommendations for the operations and efficiency of the facility. All communications will be through the Plant Manager, Bill Daniels.

   Product: The County will prepare a report after each test run with recommendations and provide a copy to the Mayor's office. This report will include standard operating procedures for start-up, operations, shut down, and maintenance.

3. Upon declaration of a water emergency by the Mayor of the City of Flint, the County will take operational control of the facility. The County will issue all communications through the Plant Manager, Mr. Daniels.

PRELIMINARY

The City will perform the following:

1. The City will perform all day-to-day activities of the facility. Mr. Daniels will continue to sign monthly reports when the plant is not operating (test or emergency).

2. The City of Flint will maintain personnel records including records of operator training and continuing education reports.

3. The City shall provide the County with its water plant test run schedule 30 days prior to commencement of the test operation. This schedule shall include dates and hours of test operation, schedules of personnel dedicated to the test operation, and an inventory of chemicals on hand. good

endorse this !!

4. The City shall maintain the facility in a state of readiness for emergency operations. This shall include but not be limited to:
   - maintain sufficient (two weeks) quantity of chemicals onsite for emergency and test operations. good
   - maintain all equipment in accordance with manufacturers' requirements and as identified in the Standard Operating Procedures (SOPs),
   - financial commitment by the City to the maintenance of the facility in a state of operational readiness.

Full agreement that plant will not operate, chem, staffing

5. The City shall maintain all necessary permits and programs as required by State and Federal government. This includes, but is not limited to, source water protection plan, process safety management plan, laboratory certification.

6. The City shall maintain all communications with their residents including communications, reports, and questions and answers.

PRELIMINARY

Again, the purpose of this agreement is for the temporary operation of the water plant during test runs and emergency operations.

Cost: The County has agreed to perform the above services based upon the following fee schedule:

Item #2 (First Page of draft) Per

(Item 2) → Test runs	$2,000.00 per week
(Item 3) → Emergency operations	$2,000.00 per week

Item #1 on first page of Draft

No charge for Item #1 ?

There are no other charges contemplated in this agreement.

Insurance: The City shall provide the necessary insurance coverage for activities on their property.

Termination: The agreement may be terminated under one of the following conditions:

1. The City hires or retains an F-1 licensed operator.

2. Upon 30 day written notification to the County that the City has not fulfilled their requirements of the agreement.

OUR reading of the agreement is open ended & continues till terminated by either party

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

JENNIFER M. GRANHOLM
GOVERNOR

STEVEN E. CHESTER
DIRECTOR

November 17, 2005

Mr. Bill Daniels, Acting Water Plant Supervisor
Flint Water Treatment Plant
4500 North Dort Highway
Flint, Michigan 48505

WSSN: 2310

Dear Mr. Daniels:

SUBJECT: City of Flint Water Treatment Plant (WTP)

This letter confirms my visit on October 27, 2005 with you and Brent White. The purpose of the visit was to discuss the following items: status of the WTP rehabilitation project, operator certification, treatment plant operation, investigation of pump submergence at the low lift station with respect to Hamilton Dam, and distribution system improvements for 2006. Each one of these items is discussed below in more detail.

Water Treatment Plant Rehabilitation

Substantial completion of Segment 5, Phase I of the WTP rehabilitation project is expected by March 1, 2006. Unit process testing and equipment shakedown of the ozone facility will begin this January. The treatment plant is expected to be capable of performing a complete test-run by next May. As we discussed, written confirmation stating the date that the WTP is capable of initiating operation needs to be provided to us.

Operator Certification

Mr. Robert Carlyon has tendered his resignation as the interim operator-in-charge (OIC) of the WTP. This latest development leaves the city of Flint without an F-1 certified operator to oversee operation and maintenance activities at the WTP.

Since Mr. Daniels has not achieved his F-1 license, the city will need to retain another interim (OIC) holding an F-1 license. As a minimum, the OIC needs to maintain an active role in various WTP operations listed below:

- Construction oversight of the on-going rehabilitation project
- Equipment shakedown
- Continuing education and operator training
- WTP test runs
- Emergency operation

The interim OIC may no longer be necessary after June of 2006 provided that Mr. Daniels obtains the F-1 license. Also, consensus from the city and the interim OIC that Mr. Daniels can operate the WTP without additional oversight from the OIC needs to be provided; otherwise, the contract with the interim OIC must be extended.

We need to hear from the city, in writing, as to what action is being taken to provide an interim OIC by no later than December 1, 2005.

Treatment Plant Operation

Completion of Phase I of the water treatment plant rehabilitation project marks the ability of the treatment plant to function as an acceptable stand-by treatment facility. To demonstrate and maintain the level of operational reliability required of this facility, some continuing level of operation will be necessary.

A proposal detailing an operating scheme for the facility must be prepared. The following operating ranges need to be established:

- Annual Basis: Propose the number of months/year the plant will be in operation.
- Monthly operation: Propose the number of hours the facility will operate in a given month.
- Weekly basis: Establish the minimum and maximum production rates and propose the number of hours of continuous operation for both these rates.

The operating ranges that the city proposes are negotiable; however, a scheme that tests all equipment, operation, and performance at varying rates is necessary. The test runs also need to be performed during critical times of the year including: peak run-off (high turbidity), summer (low flow, high temperature), and winter (low temperature).

The operating scheme must also include a plan that addresses staffing. Sufficient staffing is essential in order to maintain 24-hour operation (either for test-run or emergency operation) of the treatment facility. Based upon our discussion with plant staff, there has been a significant reduction in the number of available operators since previous plant test-runs. We are concerned whether a sufficient number of operators are available for 24-hour operation.

The city needs to determine the staffing necessary to operate the treatment facility on a 24-hour basis. Additional operators necessary for plant operation and oversight of all shifts need to be provided. Additional position(s) should require least an F-4 complete treatment license.

Following our review of the test-run proposal, we will meet with the city and plant staff to discuss test-run operation in more detail.

(5[illegible]) 764-7218

Next, if the treated water is wasted, the water must still meet the bacteriological and turbidity requirements as a condition of operational preparedness.

In addition, the operating budget for the treatment plant will need to be adequate to allow for purchase of treatment chemicals necessary to perform test-runs of the entire treatment plant.

Finally, the operating scheme for plant test-runs and mobilization of operators needs to be addressed in Flint's water system contingency plan. Emergency operation of the WTP is a crucial part of the city's water system contingency plan and the plan will need to be updated to include plant operation under this type of emergency.

Hamilton Dam

Additional field data has been obtained toward completing the low-lift pump submergence investigation; however we have not received a response from the city regarding this issue. Adequate low lift pump submergence during low flow conditions while meeting the drawdown requirements at Hamilton Dam needs to be confirmed.

Based upon the investigation, it appears that the drawdown requirements can be met; however, what is the status of the investigation and are there any conclusions? Please provide us with a summary.

Distribution System Improvements

Distribution system improvements completed since 2004 included replacement of transmission piping along Pierson Road. Major improvements planned in 2006 include: installation of new transmission main along Flushing Road and replacement of the Torrey Road pumping station. We will review distribution system issues with staff from both the Water Service Center and the WTP in more detail during our upcoming Sanitary Survey.

There are many issues noted above that the city needs to take action on. We are requesting the city to respond to us, in writing, on the Treatment Plant Operation and Hamilton Dam issue by no later than February 1, 2006. If you have any questions regarding these issues or any other water related matter, please feel free to call me at the number listed below.

Sincerely,

Michael F. Prysby, P.E., District Engineer

STEVEN E. CHESTER
DIRECTOR

August 18, 2005

Ms. Peggy Cook, City Administrator
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502-1416

WSSN: 2310

Dear Ms. Cook:

SUBJECT: City of Flint Water System
Operator Certification

We have received a copy of a resolution that establishes a professional services contract with Carlyon Consulting L.L.C. The professional services contract retains Mr. Robert Carlyon as the interim operator-in-charge (OIC) for the Flint Water Plant for fiscal year 2006. Establishment of the service contract allows the city to remain in compliance with the Michigan Safe Drinking Water Act's requirement for operator certification at the treatment plant. The contract is also important in the event that the treatment plant is needed to produce water to mitigate a water system emergency.

Next, we are assuming that Mr. Mike Brown is the distribution system OIC; please verify this. In addition, a class S-1 system shall designate one or more operators holding an S-4 or higher certificate as a back-up operator. Who is the designated back-up operator for the distribution system? An operator designation form is enclosed with this letter and can be used to answer these questions.

Finally, it is our understanding that Mr. Bill Daniels will attempt to obtain the F-1 certification next spring.

If you have any questions regarding this issue or any other water related matter, feel free to call me at the number provided below.

Sincerely,

Michael F. Prysby, P.E., District Engineer

WSSN: 2310

Dear Mr. Carlyon:

SUBJECT: City of Flint Water System
Site Visit

This letter confirms my visit on January 24, 2005 with you, Bill Daniels, Michael Brown, Brent White, and Mike Gleason. The purpose of the visit was to discuss the following items: operator certification, status of the revised Certificate of Coverage (COC), investigation of pump submergence at the low lift station with respect to Hamilton Dam, crypto/E Coli monitoring for the LT2 rules under the surface water treatment regulations, distribution system improvements for 2005 and beyond, re-issuance of the Sugar Maple Farms watermain permit, and the updated bacteriological sampling site plan. Each one of these items are discussed below in more detail.

Operator Certification

It has been brought to our attention that Jeffrey Bryson has retired as operator from the city of Flint and that you will again assume the role as the operator-in-charge (OIC) of the water treatment plant (WTP). Next, Mr. Daniels will assume many of the operating responsibilities of the WTP and will pursue the F-1 certification. Mr. Daniels may be eligible to write the F-2 and/or F-1 certification exam provided that he has satisfied the criteria established in our September 7, 1989 memo to the Advisory Board of Examiners and Item #13 from the April 18, 2003 Advisory Board meeting minutes (copies of both documents were provided to you). In addition to completing the F exam application, Mr. Daniels needs to document his plant operating experience including plant test runs and start-up & testing of new equipment installed during the WTP rehabilitation project. Finally, any additional educational requirements specified in the April 18th document must also be completed prior to writing the F-1 certification exam.

Next, the topic of hiring a temporary or (contract) OIC in the event that the current OIC is no longer available was discussed. For short-term operation, it would be acceptable to retain a temporary OIC with an F-1 license to oversee operation of the WTP while Mr. Daniels pursues the F-1 license. Prior to retaining a temporary OIC, we would be interested in discussing operations under the oversight of a temporary OIC and establish contractual responsibilities. Finally, the city will need to provide us a plan of action addressing operator certification in the event that Mr. Daniels fails to obtain the F-1 license after the first attempt.

Change in COC

The Permits Section of the Water Bureau is in the process of re-issuing Flint's COC under the General Permit No. MIG640000. The new COC will allow the City of Flint to discharge 19.2 MGD of treated filter backwash and other wastewater associated with the production of potable water from the Flint WTP.

Hamilton Dam

Field data is being obtained to complete the investigation into whether adequate pump submergence can be maintained at the low lift pump station during low flow conditions in the Flint River while meeting the drawdown requirements at the Hamilton Dam. Several attempts were recently made to induce low flow conditions in the Flint River; however, significant run-off during the month of January has delayed this effort. Please keep us and the Department of Environmental Quality's (DEQ) Dam Safety Unit updated as to the status of this investigation.

Crypto/E-Coli Monitoring

Preliminary monitoring for cryptosporidium/E-Coli monitoring under the future Long-Term 2 Enhanced Surface Water Treatment Rule was discussed. The results of the monitoring performed in accordance to an approved sampling plan prior to promulgation of the LT2 rules would be eligible for grandfathering. The results would help the city to assess the need to install the appropriate treatment based upon bin placement.

We understand that you did not proceed with this monitoring. We will keep you informed about the LT2 rule as we expect promulgation of the rule later this year.

Distribution System Improvements

Distribution system improvements are expected to commence in 2005 and include replacement of watermain along Pierson Road. Next, the city is planning to proceed with valve replacement during 2006 in Flint Park through the use of Community Development

Block Grant funds. Other water system improvements anticipated in 2006 and beyond include: replacement of transmission main along Flushing Road, additional watermain replacement in the Beech and Wellington Road area, and improvements to the Torrey Road pump station plus others. We would be interested in receiving a schedule that lists these and other distribution system improvements. Finally, has the city updated their 5-year capital improvements program (CIP)? If the CIP has been updated, we would be interested in receiving a copy for our records.

Bacteriological Sampling Site Plan

We have received a copy of Flint's updated bacteriological sampling site plan. The plan was revised to reflect changes in a few of the routine and repeat sampling locations. Also, changes in contacts (local and DEQ) were noted. Based upon our review, the updated sampling site plan is acceptable. The sampling site plan should be updated every two or three years or as needed.

Sugar Maple Farms Development

Installation of watermain to serve the Sugar Maple Farms development issued under Construction Permit #W021063 on April 29, 2002 to the City of Flint has not been completed. A request for a permit extension was made by the city last summer, however, the request was denied due to possible changes in the design and ownership of the infrastructure.

As we discussed, a new construction permit needs to be issued for this project due to our new permit application process. Please re-submit the plans and specifications with the appropriate permit application. Following our review and approval, a new construction permit will be issued for this project.

We will re-visit these issues during our next site visit this spring. If you have any questions regarding these issues or any other water related matter, please feel free to call me at the number listed below.

Sincerely,

Michael Prysby

Dear Mr. Carlyon:

SUBJECT: City of Flint Water System
2003 Sanitary Survey Update

This letter confirms my visit on December 10, 2003 with you, Jeff Bryson, Michael Brown and Glen Thomas. The purpose of the visit was to review the status of the more critical items from the city's water system 2000 Sanitary Survey.

The city has made further improvements in certain programs including; cross connection control, operator certification, customer metering, and contingency planning. Additional administrative steps have been taken which should set the stage for transmission/distribution system and pumping station improvements during 2004 and 2005. Given the improvements completed in the various programs, Flint's water system rating shall improve to **"Marginal".** Further progress, however, must be made in the following areas in order to maintain or improve the water system rating further.

1. Update the local cross connection ordinance and program. Maintain an adequate number of staff to operate the program effectively.

2. Proceed and complete the transmission main replacement projects along Beech & Wellington, Pierson Road, and Flushing Road by 2006.

3. Update the 5-year capital improvements program and provide us with a copy.

4. Complete and implement the distribution system hydraulic model for use.

5. Develop and implement a water system valve program.

6. Re-evaluate booster pumping station improvement needs and prepare a schedule.

7. Finalize Flint's Emergency Operations Plan.

For a more thorough discussion of our updated survey please reference the attached Conclusions and Recommendations document.

If you have any questions regarding these issues or any other water related matter, please feel free to call me at the number listed below.

Sincerely,

City of Flint
Evaluation Update
12/10/2003

1. **Organizational Structure & Operator Certification**

Water Dist Div (WDD) - Number of employees? 44

OIC – Level 28 (S-1)
Level 22A (forman levels) S-2s - three-four positions
Levels 12, 18, & 19 – trainee, maintainer, equip op - S-3 and S-4 certs requ for level 18 and 19 positions – status?

Updated Org. chart available? – Yes

Promoting operator cert. – job descriptions avail?
Job descr revised to reqr cert
Maintainer not updated - Both will S-4 within 2-3 yrs
Meter reading staff – status of cert. requirement?
Meter Tech – S-5

2. **Transmission/Distribution**

Hydraulic model final calibration - inconsistencies resolved? Causes?
Not Final Cal – ensure the right fire data
Test process of staff/prior to hire → once hired they will be trained
Training of staff – Status?
Data Fed & Automation Clerk will be trained

Updating of General Plan? Obtain from model, Status?
Planned for FY 04/05 – Full copy in FY 05

Utilities Dept CIP (List of mains) – what's on tap for 04? 05? Copy avail?
Beach/Welch Phasing Rd
Pierson Rd 04/05
Status of MDOT projects – some were on-hold.....
Pierson Rd was on hold – being relooked now
Other MDOT projects – Pierson looking
New rate schedule to facilitate start of the CIP – Status? – is in place

Block grant funding – any of these?
yes – Beach/Welch 04/05 Funds
yes – Pierson Rd

Security specialist looking for matching grant $ to jumpstart Item #3

Back Burner due to WTP & rite then focus on WTP plus phase II repl + low westside

3. **Pumping Stations & Storage**

P.S. #4 is in phase II - prelim

Switch-gear upgrades at Cedar Street/ Stand-by Power?

- no activity yet
- V's replaced
- Re-built motors
- switch gear motors mechanical

Pump control & replacement of swing-check valves at Westside (smaller pumps)?

Enviro. Coop. Committee to discuss Reg. issues

IPP
WP
CCCW
Remediation effort
co chaired by Gov Motors DEQ/ EPA OVR

Status of Segment 4 - on schedule? — FIN. SPR 05

City of Flint – Sanitary Survey 2003 Update
Conclusions and Recommendations
December 10, 2003

In general, our survey covers the major aspects of a water supply including: stand-by facilities, distribution, source capacity, and storage. The update of our 2003 survey shows that the City of Flint's water distribution system rating has improved to a "**marginal**" rating. The improved rating comes with several primary concerns which are discussed below in more detail.

1. The city of Flint continues to make improvements with their Cross Connection Control Program (CCCP). Annual inspections at high priority accounts are continuing and initial inspections have commenced at low priority accounts. Approximately 400 higher priority accounts (those having reduced pressure zone, RPZ, backflow preventer devices) exist and over 75% have complied with the RPZ testing requirement during 2002. Approximately 4000 low hazard accounts exist and approximately 1,500 of these accounts were inspected in 2003. The city intends to inspect all low hazard accounts at least once every three years.

   Flint's CCCP rating shall improve to a satisfactory status and is based upon the improvements made during 2002 and 2003. The Utilities Department, however, has determined that one additional cross connection inspector is needed in order to maintain adequate implementation of the CCCP.

   The Utilities Department is in the process of updating the local cross connection ordinance that will include a new fee schedule which will allow for an additional cross connection inspector. A draft ordinance was provided to us and is acceptable for program implementation. We would encourage the city to approve the new fee schedule contained in Sec. 46-43.2, since additional staffing appears necessary in maintaining an acceptable CCCP.

   Finally, the Utilities Department is revising the city's most recent CCCP (1989 document).

   The remaining CCCP elements need to be completed and are outlined below:

   - Complete the revision of the city's most recent CCCP ordinance (Ordinance No. 3267) and provide us with a copy.
   - Update the city's most recent CCCP (1989 revision). Provide us with a draft copy of the updated program for our review and comment.
   - Achieve the necessary staffing to complete the minimum number of routine inspections, maintain adequate records and reporting, and maintain an acceptable program rating.

2. Operator certification (distribution) continues to show improvement and is evidenced by the increased number of exam applicants pursuing their S-4 and S-3 licenses. The position descriptions for the Water Distribution & Sewer Maintenance Supervisor, Water Distribution Foreman, and the Water Construction Equipment Operator have been updated and now require the S-1, S-2, and S-3 licenses respectively. The position descriptions are also being revised for the Maintainer and Trainee positions and will call for acquiring the S-4 license within two or three years.

   It is evident that more attention is being given towards operation certification. Again, the city needs to continue to encourage and promote operator certification among the Utility Department operators who are involved in water system activities.

   Finally, the position descriptions for the meter reading staff are also being updated and the requirement for obtaining an S-5 license is still being considered. A review of the exam content, however, shows the majority of the exam questions arise from subjects that the meter reading staff are not involved with. An S-5 certification requirement to maintain a position as a meter reader would not be appropriate.

3. The DLZ Michigan, Inc. hydraulic model is essentially complete with the exception completing a final calibration and hiring the necessary technical and automation position(s) to utilize the model for its intended purpose. The hiring process for the new position(s) is expected to proceed following the completion of a test protocol that will be used in the screening process for prospective jobs applicants. The position(s) is(are) expected to be filled later in FY 04. The hydraulic model will also be completed and implemented for use at this time. As we discussed, the model should be used for verifying hydraulic improvements, input of hydrant and valve information, and generation of system plans and maps.

   A primary concern with the Flint water distribution system continues to rest with the condition of the piping. Many mains are in poor condition and in need of replacement. Due to budget constraints the city has not proceeded with the suggested Capital Improvements Program (CIP) for watermain replacement in 2002 and 2003. The city, however, has secured Community Development Block Grant funding and approved a new water rate structure that will allow for distribution system improvements on a yearly basis. Improvements slated for FY 04 include: replacement of distribution main along Beech and Wellington Streets and replacement of transmission main along Pierson Road. Replacement of transmission main along Flushing Road is expected to commence in FY 05.

   It is our understanding that the 5-year capital improvements program (CIP) is being updated to reflect the water system improvements that can be completed based upon the available grants and the new rate structure. Please send us a copy of the updated CIP when it becomes available.

4. A major concern continues to lie with Flint's deficient valve program. Funding has been set-aside for FY 04 and 05 for repair and exercising of distribution system valves, however, there has been little if any progress towards exercising system valves and establishing an adequate recordkeeping system. The availability of a sufficient sized workforce needed to improve the valve program continues to pose a problem. The Utilities Department will request for additional staff beginning in FY 05 to help address this program need. It would be worthwhile to prepare a schedule that outlines a valve program for implementation.

   Next, additional water department staff also appears needed to address concerns regarding repair of main breaks and completing water service orders in a timely basis. The city needs to review the workload and staffing needs that will be described by the Utilities Department and approve the additional positions needed to improve this program.

   Finally, the city has replaced the majority of it residential and commercial meters with radio read meters. This is a significant improvement and is allowing the utilities department to conduct more accurate meter reads in a shorter amount of time.

5. The Booster Pumping Station Master Plan discussed during our 2000 survey has not been prepared. However, certain improvements including: replacement of cone valves with check valves, rehabilitation of motors, maintenance of switchgear, installing new transformers, and replacing the roof at the Cedar Street facility were completed.

   Other significant pump station improvements need to be completed and include; upgrading the switchgear at Cedar Street, replacing the swing check valves on the smaller pumps at the Westside pump station, and completing pumping modifications at the Torrey Road pump station. It is our understanding that these improvements along with provisions for booster pumping station stand-by power will be included in the report for Phase II of the water treatment plant rehabilitation project. A review of critical customers downstream of the Torrey Road pump station and a determination of the need for stand-by power at this facility prior to Phase II of the water treatment plant project should be performed.

   Finally, according to our records, the water storage reservoir at the Westside Pumping Station is coming due for an internal inspection.

6. We have received an Emergency Operations Plan (EOP): Utilities, prepared by the Utilities Department that constitutes a water system contingency plan. The EOP outlines emergency procedures to be followed for the following events; source water and distribution system contamination, man-made and natural disasters, and enemy attack emergencies.

The EOP, however, does not include an outline showing mitigation of the following emergencies; failure of the 72-inch transmission main and a widespread power outage. You indicated that an emergency procedure addressing failure of the 72-inch transmission main will be prepared and included in Appendix 4 of the EOP (Technological Disaster Procedures). As we discussed, the outline needs to summarize the coordination among all parties (Utility & WTP staff, Flint, GCDC, & DWSD officials) as to who will conduct the repair. The availability of repair parts must also be ascertained.

Next, you mentioned that mitigation of a widespread power outage cannot be incorporated into the EOP since provisions for stand-by power will not be addressed until Phase 2 of the water treatment plant rehabilitation project. It may still be worthwhile to outline the procedure(s) of utilizing existing city infrastructure (storage facilities, interconnections, emergency water use reduction, etc.). This section can be left open for further revision when stand-by power issues are addressed during Phase 2.

Next, the EOP should also include a supplement that discusses other types of critical equipment failures (treatment components, pumping station, storage facilities, etc). An emergency procedure addressing this type of related emergency can also be included in Appendix 4 of the EOP.

Finally, the EOP also needs to contain a protocol for placing the WTP into service during an emergency. Although the WTP is in the midst of Segment 4 construction, an interim procedure should still be established. The start-up protocol will likely change as the rehabilitation project approaches completion. A final protocol should be developed after completion of the treatment plant rehabilitation project.

Please provide us with a copy of any additional supplements for inclusion into our copy of the EOP. We will review these and provide you with any additional comments, suggestions, and/or questions.

Utilities Department accomplishments of note—First Quarter—September, October & November 2003

- **Implemented FY 04 Water and Sewer rates as determined by the rate study.**

- **Successfully applied for $19,180,000.00 in low interest Drinking Water Revolving Fund loan monies. This will complete Segment 4 and Segment 5 of Phase I of the Water Plant Rehabilitation. Construction is anticipated to be complete by April, 2005.**

- **Successfully negotiated a water rate reduction with DWSD based upon corrected data on peaking factors that resulted in $1.9 million in savings to Flint. DWSD additional work in verifying this data will result in an additional credit of a little over $5,000 per month on the rates charged for FY 05.**

- **The commercial and industrial water meter replacement program will be completed by calendar year-end. Over 1,400 meters have been replaced to date. Significant revenue increases are expected when the program is complete and entered into the City billing system. The number of estimated water and sewer bills will likewise drop when this is completed.**

- **Over one thousand residential water accounts did not have the water meters replaced during the 1997-99 replacement program. The City has been divided into three sections and two of those sections are now complete. Nearly every address in those two sections has either had its meter replaced or has been removed from the records due to having been demolished. The third section (primarily in the North end) is proving somewhat more troublesome, but efforts have begun in that area. The program is on schedule for completion by Spring, 2004.**

- **Design of the Beech and Wellington neighborhood water main replacement project, funded by CDBG, is complete and bidding is expected to take place in January with construction to take place in the Spring, 2004. This project replaces aged four-inch water mains with eight-inch mains which will improve water quality and fire-fighting capabilities.**

- **Planning for the Pierson Road water main replacement and street reconstruction project is underway. The City obtained $450,000 in federal funding to help offset the costs of the water main work. Design work will be completed within the next quarter and bidding for the construction contract is anticipated in April or May.**

By end of JAN

Meter prog

Budget prog

Replaces 3½ miles of 16"
one of higher priority projects in the DWRF Project PLAN

Utilities Department accomplishments of note—June, July, August 2003

- Completed Water and Sewer Rate Study. ✓
- Agreed to an amendment to the water sales contract between Flint and Genesee County to more accurately reflect the actual cost of service. ✓
- Applied for a DWRF low interest loan to complete Segment 4 and 5 of the Flint Water Plant Rehabilitation—loan award to be announced in September. ✓
- Began replacement of commercial and industrial water meters—projected increases in revenue due to increased accuracy of metered sales are guaranteed to more than offset the expenditure of some $3 million. ✓
- Established a program to replace those residential meters that were missed during the original replacement program—30% of the City has been completed. ✓
  In these areas
- Contracted for design of Beech and Wellington Streets water main replacement utilizing CDBG funds for infrastructure replacement.
  waiting for spicer for final plans
- Completed revisions to the proposed Sewer Use Ordinance to address the objections raised by General Motors and Delphi; revised ordinance under review by Law Office, General Motors and Delphi.
- Established an interdepartmental committee to address Stormwater regulatory compliance issues.
- Established a joint General Motors/City of Flint Environmental Cooperation Committee to improve communications and foster better working relationships.

PRESENTED: APR 09 2003
ADOPTED: APR 09 2003

Submission # 03EFM0203

RESOLUTION AUTHORIZING ENTERING INTO A REVISED CONSENT ORDER WITH THE MDEQ FOR COMPLETION OF THE REHABILITATION OF THE FLINT WATER PLANT

BY THE EMERGENCY FINANCIAL MANAGER:

In 1999, the City of Flint entered into a consent order with the Michigan Department of Environmental Quality for the rehabilitation of the Flint Water Plant. That agreement included a schedule for completion of Phase I of this project. Due to the fact that the City failed to qualify for a Drinking Water Revolving Fund loan last year, it is now impossible to meet the schedule included in the original order. Therefore, the MDEQ has agree to revise the original consent order to account for the delay and this revised consent order will have a new schedule for completion of the work..

BE IT RESOLVED that the appropriate City officials are hereby authorized to enter into a revised consent order with the MDEQ for the completion of the rehabilitation of the Flint Water Plant.

MODIFICATION OF CONSENT ORDER

The Department of Environmental Quality ("DEQ"), Water Division (WD) and the City of Flint ("City") entered into Consent Order No. P-99009 ("Consent Order"), which became effective on August 31, 1999. The Consent Order entered between the DEQ and the City included requirements for the upgrade of the City's municipal water treatment plant. On December 13, 2002, the City sent a letter to the DEQ requesting a one year extension of the timelines outlined in Section III. Compliance Program of the Consent Order. The DEQ and its Director are authorized under Section 15 (MCL 325.1015) and Section 16 (MCL 325.1016) of the Michigan Safe Drinking Water Act, 1976 P.A. 399, as amended, Administrative Rule 325.1028, and Section 78(2) of the Administrative Procedures Act (MCL 24.278(2)) to enter into and enforce the conditions of the Consent Order. By entry of this Modification of Consent Order, the DEQ and the City agree and stipulate to the following modifications of the Consent Order:

1. Paragraph 3.1.d and 3.1.e of the Consent Order shall be modified to read as follows:

   Except as provided elsewhere in the Consent Order, the City agrees to complete renovations to the water treatment plant according to the following schedule:

   (d) Phase I-Segment 4: Softening with lime feed including ferric bulk storage tanks, filter rehabilitation, raw water pump rehabilitation, filter backwash residual management, locker and lunchroom facilities.

   Construction permit issued by DEQ on June 10, 2002

   Notice to proceed on or before October 1, 2003

   Segment construction completed and capable to initiate operation on or before March 1, 2005

(e) Phase I-Segment 5: Ozone facilities

Issuance of construction permit on or before June 30, 2004

Notice to proceed on or before October 1, 2004

Segment construction completed and capable to initiate operation on or before June 1, 2006

2. The City shall pay stipulated penalties outlined in paragraph 4.1 of the Consent Order for failure to comply with the modified subsections (d) & (e), paragraph 3.1 above.

3. In addition to penalties required under paragraph 4.1 of the Consent Order, the City shall pay accrued stipulated penalties in the amount of **FIVE THOUSAND TWO HUNDRED ($5200) DOLLARS** to address and resolve the City's past status of non compliance (September 21, 2002-December 13, 2002) with section III. Compliance Program of the Consent Order. This penalty shall be waived only upon the City's adherence with the modified subsections (d) & (e), paragraph 3.1 above. Payment shall be made within thirty (30) days after a written demand is made by the MDEQ.

The DEQ and the City agree and stipulate that all other terms and conditions of the Consent Order are not altered or amended by the entry of this Modification of Consent Order. The DEQ and the City further agree and stipulate that the enforcement provisions of the Consent Order, including paragraph 4.1, shall apply to the terms and conditions of this Modification of Consent Order. The DEQ and the City stipulate that this Modification of Consent Order shall become effective on the date that it is signed by the Chief of the DEQ, Water Division.

Signatories

The undersigned CERTIFY they are fully authorized by the party they represent to enter into this Modification of Consent Order to comply by consent and to EXECUTE and LEGALLY BIND that party to it.

CERTIFIED MAIL

Mr. Edward Kurtz,
City of Flint
1101 South Saginaw
Flint, Michigan

Dear Mr. Kurtz:

SUBJECT: Water Division Program Updates

Enclosed are status reports for several programs administered by the Department of Environmental Quality (DEQ), Water Division, Shiawassee District.

Status reports are provided for the following program areas:

1. Water Treatment Plant
2. Water Distribution System
3. Wastewater Treatment Plant
4. Industrial Pretreatment Program
5. Municipal Storm Water Program

In addition, also enclosed is a copy of a letter from the DEQ Water Division's enforcement unit concerning a contested case hearing regarding the National Pollutant Discharge Elimination System permit for the wastewater treatment plant.

These reports summarize the DEQ's position regarding the program areas. The city has been working diligently in many of these areas, but there are many issues that still need to be addressed.

If questions arise you may contact the DEQ staff person that prepared the report or you may contact me directly.

Sincerely,

Timothy A. Benton, P.E., Supervisor
Field Operations, Shiawassee District
Water Division

Status Report
City of Flint
Water Treatment Plant

November 25, 2002

Prepared By: Michael F. Prysby, P.E.
District Engineer
Water Division
DEQ – Shiawassee District Office

We understand, based on a September 12, 2002 letter from the Environmental Assistance Division (EAD) that the City of Flint requested Segment 4 of the water treatment plant upgrade to be placed on the FY03 Project Priority List (PPL). A more recent letter from EAD (October 28, 2002) states that the Drinking Water Revolving Loan Fund (DWRF) DWRF Project No. 7010-04 is no longer within the fundable range for Fiscal Year (FY) 2003. The project will remain on the list as a "Contingency Project" pending potential expansion of the fundable range.

The potential delay of Segment 4 may jeopardize the city's ability to maintain the compliance schedule set forth in Section III. Compliance Program of the Consent Order signed on August 31, 1999. There are however, provisions within the Consent Agreement (Sections II., VI., & VII.) that may allow the city to be granted an extension of the deadline(s) contained in Section III. However, it is incumbent upon the city to make a written request for such an extension. The request shall include as a minimum the following items:

- Provide the DEQ with a written notice describing the delay and identifying the specific deadlines that will not be met.
- Make a request for an extension of the deadline (length) and specific date on which the obligation will be met.
- Discuss measure(s) to minimize the delay.

The DEQ is aware of the financial issues that face the city and that this situation will complicate matters when attempting to propose a new compliance date.

It is important to make all attempts to maintain compliance with the Consent Agreement. The request for an extension is the next step to help ensure this, and will also help to avoid penalties as described in Section IV.

Order No. P-99009
WSSN: 2310

/

CONSENT ORDER

The City of Flint ("City") and the Michigan Department of Environmental Quality ("MDEQ") agree to the following terms.

I. BACKGROUND RECITALS

1.1 The MDEQ has the authority to enforce the Michigan Safe Drinking Water Act, 1976 PA 399, as amended, MCL 325.1001 et seq.; MSA 14.427 (1) et seq.; and administrative rules promulgated thereunder, Michigan Administrative Code 1995 AACS R325.10101 et seq.; (hereinafter referred to as the Act).

1.2 The City operates a community water system to serve the citizens of the City of Flint and other customers. The City purchases water from the Detroit Water and Sewerage Department through a single pipeline. In the event of a failure of the pipeline or other extended interruption in supply from the pipeline, the City would need to use the existing standby facilities.

1.3 The MDEQ, its Director, and his authorized designee and City are authorized under Section 15 (MCL 325.1015) and Section 16 (MCL 325.1016) of the Act, Administrative Rule 325.10208, and Section 78(2) of the Administrative Procedures Act (MCL 24.278(2)) to enter into, comply with, and enforce the positions of this Consent Order. The MDEQ acknowledges that this enforcement action embodied by this Consent Order entitles the City to an additional twenty-five (25) points under Section 5406 of the Safe Drinking Water Assistance Act (MCL 324.5406).

1.4 This Consent Order shall be considered a Final Order of the MDEQ, and shall become effective on the date it is signed by the Chief of the Drinking Water and Radiological Protection Division (DWRPD), designee of the MDEQ Director.

1.5 The City agrees to fully comply with all provisions of the Act, its Administrative Rules, and this Consent Order. The City and the MDEQ acknowledge that the signing of this Consent Order is to provide for the renovation of the Flint Water Treatment Plant (the "Facility"), according to the terms and schedule set forth herein.

In this regard, the City has submitted a project plan to the MDEQ for the purpose of obtaining funding under the Drinking Water Revolving Fund (DWRF) program. Furthermore, the rehabilitation of the Facility as described by the approved project plan will assure the City an adequate and reliable supply of drinking water on a continuous basis. The MDEQ acknowledges that the project set forth in the project plan fulfills the reliability requirements of the Act.

II. EXTENSIONS

2.1 The City and the MDEQ agree that the Chief of the DWRPD may, at his sole discretion, grant the City an extension of the specified deadlines set forth in this Consent Order. Any extension shall be preceded by a timely written request, received by the MDEQ no later than forty five (45) business days prior to the pertinent deadline, which shall include:

(a) An identification of the specific deadlines(s) of this Consent Order that will not be met.

(b) A detailed description of what will prevent the City from meeting the deadline(s).

(c) A description of the measures the City has taken and/or intends to take to meet the required deadline.

(d) The length of the extension requested and the specific date on which the obligation will be met.

The Chief of the DWRPD shall respond promptly to such requests.

2.2 No formal advice, guidance, suggestions, or comments by the MDEQ regarding reports, work plans, plans, specifications, schedules, or any other writing submitted by the City will be construed as relieving the City of its obligation to obtain written extensions under this Consent Order, unless such extensions are specifically waived in writing by the MDEQ.

III. COMPLIANCE PROGRAM

3.1 Except as provided elsewhere in this Consent Order, the City agrees to renovate the Facility according to the following schedule (although it may proceed more quickly if the City so chooses):

(a) 1999: Electrical maintenance facility, operations center, boiler facility, distribution SCADA system, dual electrical service, rapid mix facilities, flocculation facilities, and interconnection structure.

Issuance of construction permit July 1, 1999
Notice to proceed September 21, 1999
Segment construction completed by December 22, 2000

(b) 2000: [redacted] flume rehabilitation and chemical feed systems.

Issuance of construction permit June 30, 2000
Notice to proceed September 21, 2000
Segment construction completed by December 22, 2001

(c) 2001: Filter rehabilitation, electrical rehabilitation including primary substation switchgear and pump station #4 motor control centers.

Issuance of construction permit June 30, 2001
Notice to proceed September 21, 2001
Segment construction completed by December 22, 2002

(d) 2002: Upflow softening basins, recarbonation facilities, treatment processes SCADA system and residuals treatment.

Issuance of construction permit June 30, 2002
Notice to proceed September 21, 2002
Segment construction completed December 22, 2003

(e) 2003: Ozone facilities, raw water pumping improvements and site improvements.

Issuance of construction permit June 30, 2003
Notice to proceed September 21, 2003
Segment construction and any remaining items from previous years complected by December 22, 2004

The City reserves the right to remove items from the compliance program that the Michigan Department of Environmental Quality determines are unnecessary or that are not necessary to protect public health through adequate treatment of water for drinking and household purposes.

3.2 The City shall provide third party construction certification by a registered professional engineer when project segments have been completed in accordance with the approved plans.

IV. SETTLEMENT OF VIOLATIONS

4.1 For each failure to comply with the provisions of Section III, Compliance Program, of this Consent Order, the City shall be given thirty (30) days in which to correct the violation without incurring a stipulated penalty. Thereafter, the City shall pay to the State of Michigan the sum of $100 per violation per day for thirty-one (31) to ninety (90) days of violation, and $500 per violation per day for each day of violation thereafter. Payments shall be paid within thirty (30) days after a written demand is made by the MDEQ.

4.2 The City shall make the payments set forth above by certified or cashier's check made payable to the "State of Michigan" and mailed to the MDEQ, Revenue Control Unit, P.O. Box 30657, 300 South Washington Square, Suite 457, Lansing, Michigan 48909-8157. To ensure proper credit, all payments made pursuant to this Stipulation should include Payment Identification Number DWD _____.

V. DISPUTE RESOLUTION

5.1 Any dispute that arises under this Consent Order shall initially be the subject of informal negotiations between the parties. The period for informal negotiations shall end when the MDEQ provides a written statement setting forth its proposed resolution of the dispute to the City. The City and the MDEQ agree that the informal negotiation period tolls any statute of limitation or other judicial or administrative court filing period of limitation regarding items particularly in dispute.

VI. FORCE MAJEURE

6.1 The City shall perform the requirements of this Consent Order within the time limits established herein, unless performance is prevented or delayed by events which constitute a "Force Majeure." Any delay in the performance attributable to a "Force Majeure" shall not be deemed a violation of the City's obligations under this Consent Order. Furthermore, payments under Section IV, Settlement of Violations, shall not accrue during any period that constitutes "Force Majeure."

6.2 For the purpose of this Consent Order, "Force Majeure" means an occurrence or nonoccurrence arising from causes beyond the control of and without the fault of the City, such as: an Act of God; untimely review of permit applications or submissions by the MDEQ or other applicable authority; and acts or omissions of third parties that could not have been avoided or overcome by the City's diligence, that delay the City's performance of an obligation under this Consent Order.

6.3 "Force Majeure" does not include, among other things, unanticipated or increased costs, or changed financial circumstances, except as set forth in Section VII, Available Funding, of this Consent Decree.

6.4 The City shall notify the MDEQ, DWRPD Supervising District Engineer in Morrice by telephone at 517-625-4682, within forty-eight (48) hours of discovering any Force Majeure event, which causes a delay in its compliance with any provision of this Stipulation. Written notice shall be submitted withing ten (10) calendar days and shall describe in detail the anticipated length of delay, the precise cause or causes of delay, and the measures taken by the City to prevent or minimize the delay. The City shall adopt all reasonable measures to avoid or minimize any such delay.

6.5 If the parties agree that the delay or anticipated delay was beyond the control of the City, the parties may agree upon an appropriate modification to this Consent Order. The burden of proving that any delay was beyond the reasonable control of the City, and that the City has met all the requirements of this Section, is on the City.

6.6 An extension of one (1) compliance date based upon a Force Majeure event does not qualify the City for an extension of subsequent compliance dates, unless the parties agree that subsequent activities and compliance dates are dependant on completion of prior activities.

VII. AVAILABLE FUNDING

7.1 The City and MDEQ agree that the City's obligation to meet the schedule of activities set forth in Section III, Compliance Program, is contingent upon the City having accumulated total DWRF super-priority funding in at least the following amounts by the following years:

(a) 1999: $4,000,000
(b) 2000: $10,000,000
(c) 2001: $16,000,000
(d) 2002: $22,000,000

However, the City shall only be excused under this paragraph if the City has made a good faith attempt to receive DWRF funding in each year stated above. In the event that the City does not receive and accumulate DWRF funding in at least any of the above-stated amounts, then the MDEQ and the City shall renegotiate the schedule contained in Section III of this Consent Order, although the City shall not be excused from performing the activities set forth therein. The City acknowledges

that the above-stated amounts are not meant to cover the full cost of the contemplated Facility rehabilitation and that it is the City's responsibility to cover such additional amounts.

VIII. GENERAL PROVISIONS

8.1 With respect to any violations not specifically addressed and resolved by this Consent Order, the MDEQ reserves the right to pursue any other remedies to which they are entitled for any failure on the part of the City to comply with the requirements of the Act and its Administrative Rules.

8.2 Notwithstanding any other provision of this Consent Order, an enforcement action may be brought by the MDEQ pursuant to the Act, its Administrative Rules, or other statutory authority where the City may present an imminent and substantial hazard to the public health or to the environment or is endangering or causing damage to the pubic health or the environment.

8.3 This Consent Order in no way affects the City's responsibility to comply with any other applicable state, federal, or local laws or regulations.

8.4 Nothing in this Consent Order shall be construed as an admission of liability or serve as an admission of any fact in any judicial court or administrative court on the part of the City.

IX. TERMINATION

9.1 Except as provided elsewhere in the Consent Order, this Consent Order shall remain in full force and effect until expressly terminated by a written Notice of Termination issued by the Chief of the DWRPD. The City may request that the Chief issue a written Notice of Termination at any time after achieving compliance with this Consent Order. Such a request shall consist of a written certification that the City has fully complied with all of the requirements of this Consent Order. Specifically, this certification shall include:

(a) The date of completion of each segment of the compliance program in Section III; and

(b) A statement that all required information has been reported to the Supervising District Engineer.

The Chief of the DWRPD may also request additional relevant information.

SIGNATORIES

The undersigned certify that they are fully authorized by the party they represent to enter into and execute this Consent Order and to legally bind that party to it, that they have executed this Consent Order solely upon their own judgment and that they have read and fully understand the content and legal consequences of this Consent Order.

Resolution Authorizing Entry into Consent Order With Michigan Department of Environmental Quality

BY THE MAYOR:

Pursuant to its authority under the Michigan Safe Drinking Water Act, 1976 PA 399, as amended, MCL 325.1001 et seq.; MSA 14 427(1) et seq, the Michigan Department of Environmental Quality (MDEQ) has requested that the City renovate the Flint Water Treatment Plant, so as to ensure the Water Plant will continue to provide a reliable source of water in the event of a failure or extended interruption in the water pipeline from Detroit

The City and MDEQ have negotiated a Consent Order, see attached, whereby the City has agreed to a schedule for renovations of the Water Plant. In exchange for its commitment to the schedule, the City shall receive an additional twenty-five (25) points under the Safe Drinking Water Assistance Act.

The City's obligation to meet the schedule of activities set forth in the Consent Order is contingent upon the City having accumulated total Safe Drinking Water Assistance Act revolving fund super-priority during the years 1999 – 2002.

Further, in the event the City is not awarded funding under Safe Drinking Water Assistance Act during years 1999 – 2002 of the Consent Order, the schedule for renovations is re-negotiable.

RESOLVED, that the appropriate City Officials are hereby authorized to enter into the above described Consent Order with MDEQ A project will be established for matching estimated revenue and appropriations.

Status Report
City of Flint
Water Distribution System

November 25, 2002

Prepared By: Michael F. Prysby, P.E.
District Engineer
Water Division
DEQ – Shiawassee District Office

On November 18, 2002, a meeting was held at the Flint Water Treatment Plant between Mr. Robert Carlyon, Mr. Jeff Bryson, Mr. Michael Brown, Mr. Glen Thomas, and staff of the Department of Environmental Quality (DEQ). The purpose was to review the status of the more critical items from the city's water system 2000 Sanitary Survey. The amount of progress made in the areas discussed will help to determine whether an improvement in Flint's overall water system rating shall apply. Specific items are listed and discussed below in more detail:

1. The City of Flint has made significant improvements with their Cross Connection Control Program (CCCP). Based upon the July 12, 2002, letter from the city and our most recent discussion, routine inspections have resumed. A total of 376 higher priority accounts (those having reduced pressure zone, RPZ, backflow preventer devices) have been identified, and over 70% have complied with the testing requirement for this year. Routine inspections are being conducted at least once a year at these locations. Also, routine inspections have commenced among the lower priority accounts (4,160 total). The city intends to inspect these locations at least once every two to three years. This inspection frequency is acceptable, however, it appears that an additional part-time position will be needed to accomplish this.

   The Utilities Department will propose a new fee schedule associated with the CCCP that will allow for additional staffing to fully implement the program. We would encourage the city to approve the new fee schedule as this will assist the Utilities Department in adequately implementing the CCCP.

   Flint's CCCP's is now rated marginal. Additional program elements are needed in order for the program to obtain a satisfactory rating and are listed below:

   - Update the city's most recent CCCP (1989 revision). It may be worthwhile to reference Appendix B – "Outline of Local Program" in our Cross Connection Rules manual when updating the city's program. Please provide us with a draft copy of the updated program for our review and comment.
   - Submit a report detailing accomplishments made in 2002, and what is expected to be accomplished during 2003.
   - Achieve the necessary staffing to complete the minimum number of routine inspections.

2. Operator certification (distribution) has also improved since the time of our survey. This is evidenced by the increased number of exam applicants pursuing S-4 and S-3 licenses. The S-3 and S-4 license is now required by the city for the Water Construction Equipment Operator (Level 19) and the Water Distribution Maintainer

(Level 18) positions and will be incorporated into the job description. Finally, the city may require their meter reading staff to obtain the S-5 license.

It is evident that more attention is being given towards operator certification. The city needs to continue to encourage and promote operator certification among the Utility Department operators who are involved in water system activities.

Please submit a copy of the new employee organizational chart for the Utilities Department.

3. The DLZ Michigan, Inc. hydraulic model is essentially complete with the exception of resolving several inconsistencies noted in various locations. DLZ will assist in training the Utilities Department staff on using the model for verifying hydraulic improvements, input of hydrant and valve information, and generation of system plans and maps.

   Our main concern with the Flint water distribution system continues to rest with the condition of the piping network. Many mains are in poor condition and in need of replacement. Due to budget constraints, the city has not preceded with the suggested Capital Improvements Program (CIP) for watermain replacement. It appears that 2004 may the earliest in which the city may initiate a CIP for watermain replacement.

   A new water rate schedule is anticipated and will play a role in determining the timing of the CIP and the amount of main that can be replaced on a yearly basis. Some additional local block grant funding may allow the city to complete additional improvements. The city must prepare a revised CIP for watermain replacement after the new rate schedule is established.

4. Certain segments of Flint's water utility's O&M programs remain in need of improvement and are attributed to an insufficient amount of time, and/or number of qualified operators being committed to various program activities. Of greatest concern is the city's deficient valve program. The Utilities Department will be making a request for additional staffing to address this deficiency. The possibility of retaining a private contractor for valve exercising is also being looked into. The city needs to review the workload and determine the workforce needed by the Utilities Department to improve this program. Any additional positions that are needed should be approved and filled.

   Next, the city has replaced the majority of it residential meters with radio read meters and will proceed in replacing commercial accounts with radio reads next year. This constitutes an improvement as it will allow the department to conduct meter reads in a shorter amount of time.

   Finally, the Utility Department discontinued chlorination earlier this year at both the Cedar Street and Westside booster pumping stations. Distribution system chlorine residual levels, however, have not been negatively impacted.

5. The Booster Pumping Station Master Plan discussed during our 2000 survey has not been prepared. However, some station improvements were completed. This

included installing new transformers and incoming electrical service at the Cedar Street Pump Station along with replacing the cone valves with power check valves for the second pump. Also, the roof at the Cedar Street facility was replaced.

There are other items that remain to be completed. These include: upgrading the switchgear at the Cedar Street Pump Station; replacing the swing check valves on the smaller pumps at the Westside Pump Station; and completing pumping modifications at the Torrey Road Pump Station. We would like to hear from the city as to when these improvements can be scheduled.

6. The Watermain Plan Review Procedure submitted to us last July has been revised. Please provide us with a copy of the updated procedure.

7. We have not received an updated water system Contingency Plan that addresses other potential distribution system emergencies, in addition to the failure of the 72-inch pipeline. Such emergencies could include a bacteriological contamination episode, a large main break, a significant backflow incident, or (as previously discussed) a loss of water pressure within the Flint distribution system. The revised plan needs to outline the mitigation procedures of these potential emergencies. It was mentioned that the Genesee County Emergency Coordination would be utilized during a water-related emergency. Please send us a copy of this program and/or document describing the procedure(s) that would be followed for our review and comment.

   Next, we did not receive discussion (as part of the Contingency Plan) outlining a suggested protocol in the event of an emergency repair of the 72-inch pipeline within Genesee County. This needs to involve coordination among all parties (Utilities Department staff, City of Flint, Genesee County Drain Commissioner, and Detroit Water and Sewerage Department officials) as to who will conduct the repair. The availability of repair parts must also be ascertained.

   Finally, it is our understanding that the city has accepted a grant from the U.S. EPA for a vulnerability assessment which will also require having an adequate emergency response plan in place. Your department will also need to address water system security measures as part of the assessment and these issues should be summarized in the Contingency Plan. As we discussed, we would be willing to meet with you to review Contingency Planning in more detail and provide further technical assistance.

The city has completed improvements in certain programs and has taken administrative steps towards addressing others. The water rate study (recently awarded) should recommend a new water rate structure to adequately address the needs of the Flint water system. City administration needs to adjust the water rate accordingly in order to allow a budget that promotes on-going capital improvements and improved operation.

In addition, the city has re-implemented the Cross Connection Control Program and has taken steps towards addressing operator certification, however, other critical water system improvements are needed. Therefore, the overall rating for the distribution system shall remain at "Deficient." In order to improve the rating, significant progress

towards addressing Items #3, #4, and #7 are needed. We will plan to re-evaluate Flint's water system again in 2003.

Status Report – Facility Inspection **November 25, 2002**
City of Flint
Wastewater Treatment Plant (WWTP)
National Pollutant Discharge Elimination System (NPDES) Permit No. MI0022926

Prepared By: Charles M. Bennett, P.E.
Environmental Engineer
Water Division
DEQ – Shiawassee District Office

On November 13, 2002, staff of the Department of Environmental Quality (DEQ), Water Division (WD) visited the City of Flint WWTP for the purpose of conducting an inspection of the facility relative to the referenced discharge permit. Mr. Mark Fulks, P.E., Flint Water Pollution Control (WPC) Facilities Engineer, discussed the facility operation with Mr. Charles Bennett of the WD, then led a tour of the plant. Mr. Bennett later met with Mr. Robert Case, WPC Supervisor, and Mr. Fulks to discuss the facility operation in greater detail.

Given the city's current financial situation, our department was concerned that operation and maintenance (O&M) activity at the WWTP could be compromised. Mr. Case indicated that although operation has been difficult the past few months, the WWTP budget has been restored, and money designated for sewer operation is now available for use. The ash lagoon outfall elimination project is now scheduled to begin, and at least two significant O&M projects: the NW Pump Station (PS) Interceptor, and the 3rd Avenue PS repairs will move forward.

The inspection included the incinerator building where repair of a sludge-cake conveyor system was underway due to fire damage. A parallel conveyor system was in operation and sludge incineration was proceeding normally.

There was a strong odor emanating from the grit handling building. Mr. Fulks indicated that the grit containers had not been emptied for some time since it had not rained recently. While we realize that the greatest accumulation of grit occurs during and immediately following rain events, due to scouring of the collection system, grit containers must still be emptied on a regular basis to minimize odor. We recommend emptying grit containment on a regularly scheduled basis rather than only when the containers become full.

All aspects of security at the WWTP should be examined and hardened. We noted that the dechlorination building was unlocked, and a one-ton cylinder was stored outside the building. Also, the WWTP and Genesee County Drain Commissioner (GCDC) share a common entrance on Beecher Road. This gate is open and unattended during business hours. We recommend the city work with the GCDC to strengthen this and other common security weaknesses.

There are housekeeping needs at the plant which are currently not being addressed. Grounds are poorly tended and many building areas are unkempt. Although these things may not directly affect water quality, our experience suggests that pride develops in having well-maintained facilities, which in turn tends to enhance job satisfaction and improve the quality of plant operation.

It was mentioned that approximately 12 operators at the plant need hazardous waste operations (HAZWOPER) training. Please review all personnel training needs and update as appropriate.

The Flint WWTP continues to operate at a lower than normal capacity due in part to the Buick City closure. We understand that the city had previously discussed with the GCDC the

possibility of selling some available treatment capacity to Genesee County. Please provide an update on the status of those negotiations.

The permit issued September 29, 2000, has been contested by the city and stayed by the Administrative Law Judge. Therefore, the facility operates under the conditions of the former permit, issued October 3, 1988. At the time of the inspection, the effluent was clear and the facility appeared to be in substantial compliance with the permit.

Status Report
City of Flint
Industrial Pretreatment Program

November 22, 2002

Prepared By: Carla Davidson
Environmental Quality Analyst
Water Division
DEQ – Shiawassee District Office

This report is written to describe the status of the City of Flint's Industrial Pretreatment Program (IPP). Please see the attached District Compliance Agreement (DCA), dated October 14, 2002, which details the outstanding items of noncompliance. The DCA was developed in response to continued noncompliance with state and federal pretreatment requirements verified during a Pretreatment Compliance Inspection (PCI) conducted on August 29, 2002.

To date, the City of Flint has submitted a revised Sewer Use Ordinance (SUO) and attorney certification requested in item 4 by the due date. The SUO includes enforceable local limits as required under Administrative Consent Order ACO-SW99-013 (ACO). The SUO has not yet been fully reviewed to ascertain if it is approvable. The attorney certification is acceptable as submitted.

Please note that significant city resources will need to be devoted towards completing the actions specified in the DCA. Successful completion of these tasks will require maintaining sufficient staffing levels (retaining a minimum of 4.4 FTE IPP employees) and resources. Failure to comply with the DCA may result in further enforcement actions.

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
SHIAWASSEE DISTRICT OFFICE

JOHN ENGLER
GOVERNOR

RUSSELL J. HARDING
DIRECTOR

October 14, 2002

IN THE MATTER OF:

MICHIGAN DEPARTMENT OF ENVIRONMENTAL QUALITY// AND THE CITY OF FLINT//	**DISTRICT COMPLIANCE AGREEMENT** **NPDES Permit No. MI0022926**

On August 29, 2002, staff from the Surface Water Quality Division (SWQD), Michigan Department of Environmental Quality (MDEQ) conducted a Pretreatment Compliance Inspection (PCI) at the City of Flint (the City) Wastewater Pollution Control Facility. The MDEQ alleges that the City continues to be in noncompliance with the terms and conditions of Part I.C., Federal Industrial Pretreatment Program (FIPP) National Pollutant Discharge Elimination System (NPDES) Permit No. MI0022926, issued on October 3, 1988, which states that the permittee shall comply with Rules 323.2301 through 323.2317 of the Michigan Administrative Code (Part 23 Rules), the General Pretreatment Regulations for Existing and New Sources of Pollution (40 CFR Part 403), and the approved FIPP. The MDEQ alleges that the City continues to fail to adequately implement the requirements of its approved IPP, and that the City is in noncompliance with state and FIPP requirements.

MDEQ's letter dated September 6, 2002, alleged that the City failed to adequately implement its Enforcement Response Plan (ERP), provide adequate staffing to implement the approved FIPP, reissue permits for significant industrial users (SIUs) within 180 days of expiration, and bring nondomestic users into compliance. In addition, the MDEQ alleged that the City did not meet the requirements of NOV 12 01 01 001 L within the required timeframes, and has not yet submitted a final Sewer Use Ordinance (SUO) and attorney certification for final MDEQ approval.

In response to the allegations made by the MDEQ, the City and the MDEQ agree to the following course of action, with the explicit understanding that the City does not offer or imply any acceptance of these allegations by entering into this agreement:

1. The City hereby agrees that it shall take timely enforcement action as described in its 1993 Enforcement Response Plan (ERP), after properly verifying noncompliance and identifying a suspected perpetrator.

2. The City hereby agrees that it shall take timely enforcement action as described in its proposed ERP after properly verifying noncompliance and identifying a suspected perpetrator. This commitment shall be effective immediately after final MDEQ approval of the proposed ERP and the effective date of the City's proposed SUO following its enactment.

3. The City hereby agrees that it shall establish Special Alternative Limits for benzene, toluene, ethyl benzene, and xylenes in the sanitary sewer use permits for Lockhart Chemical and Oil Chem, Inc., in accordance with the procedures in its proposed SUO, within 30 business days of the effective date of the SUO following enactment.

4. By **October 15, 2002**, the City hereby agrees to submit an approvable, final revised draft of its proposed SUO, along with an attorney certification, regarding its legal enforceability, to the MDEQ for its review.

5. By **November 30, 2002**, the City hereby agrees to provide documentation to the MDEQ of its review and response to the following items submitted to the City on August 29, 2002 by Lockhart Chemical, as required under Part III.A of Lockhart Chemical's sanitary sewer use permit:

   a. Precipitation Runoff Report;
   b. Map of its facility and wastewater collection and drainage systems; and
   c. Slug Discharge Control Plan.

   The City shall respond by either approving the submittals or taking appropriate enforcement action to compel this company to achieve compliance with its permit.

6. By **November 30, 2002**, the City hereby agrees to provide documentation to the MDEQ of its review and response to the following items submitted to the City on August 21, 2002, by Oil Chem, as required under Part III.A of Oil Chem's sanitary sewer use permit:

   a. Precipitation Runoff Report;
   b. Map of its facility and wastewater collection and drainage systems; and
   c. Slug Discharge Control Plan.

   The City shall respond by either approving the submittals or taking appropriate enforcement action to compel this company to achieve compliance with its permit.

7. By **December 31, 2002**, the City hereby agrees to provide documentation to the MDEQ of its efforts to either cause Oil Chem, Inc., to stop diluting its centralized waste treatment wastewater with other wastewaters or establish fixed alternative limits, using the Combined Waste stream Formula, for the Oils Treatment and Recovery subcategory of the Centralized Waste Treatment category of industry in Oil Chem, Inc.'s sanitary sewer use permit.

8. By **December 31, 2002**, the City hereby agrees to provide documentation to the MDEQ of its efforts to bring Hurley Medical Center into compliance with its sanitary sewer use permit and Erwin Industries (formerly Plastics Research) into compliance with applicable sanitary sewer ordinances.

9. By **December 31, 2002**, the City hereby agrees to provide a written description to the MDEQ of its planned program for regulating restaurants whose sanitary sewer discharges plug receiving sewers.

10. By **December 31, 2002**, the City hereby agrees to submit to the MDEQ a letter either describing its efforts to fill the currently vacant Environmental Compliance Chemist position, in order to maintain an FIPP staffing level of at least 4.4 full-time equivalents, or confirming that this position has been filled.

11. By **December 31, 2002**, the City hereby agrees to provide written confirmation to the MDEQ that it has sampled and tested the discharges of SIUs regulated under applicable pretreatment standards for all relevant parameters at least once during 2002.

If the City will be unable to complete any action by a date agreed to herein, the City may request, with explanation, a mutually agreeable extension of the scheduled completion date by letter to MDEQ.

It is understood and agreed by the City and the MDEQ that compliance by the City with this agreement resolves the matters raised in the MDEQ letter, dated September 16, 2002, regarding its PCI conducted on August 29, 2002, and the MDEQ Notice of Violation 12 01 01 001 L.

Except as provided above, it is understood and agreed that compliance with this agreement does not constitute a release or waiver of liability for past or continuing violations of Part 31 of the Natural Resources and Environmental Protection Act, Act 451, PA 1994, as amended, or Part I. C., FIPP, NPDES Permit No. MI0022926, issued on October 3, 1988, which states that the permittee shall comply with Rules 323.2301 through 323.2317 of the Michigan Administrative Code (Part 23 Rules), the General Pretreatment Regulations for Existing and New Sources of Pollution (40 CFR Part 403), and the approved FIPP.

This agreement shall expire on **March 15, 2003.**

City of Flint
Municipal Separate Storm Sewer (MS4) Permit

Prepared By: Cheryl Bartley
Environmental Quality Analyst
Water Division
DEQ – Shiawassee District Office

In 1992, the Federal Regulations began requiring permits for storm water discharges. As part of those regulations, municipalities with separate storm sewer systems which serve a population of 100,000 or more were required to obtain permit coverage.

The City of Flint was issued a National Pollutant Discharge Elimination System (NPDES) Permit (MI0053864) for the storm water discharges on January 29, 1996. This permit was reissued on September 26, 2001. Please review your permit for details regarding the requirements.

Upon reviewing our permit file, it has been noted that the City of Flint has missed a compliance date set forth in NPDES permit. Per Part I.C.1.b., of NPDES Permit No. MI0053864, the City of Flint was required to submit an annual report describing their progress towards compliance with the permit on or before October 1, 2002. In addition, the annual report shall include an approvable storm water management program plan.

The City of Flint is currently non-compliant with the terms and conditions of NPDES Permit No. MI0053864.

Morrice, Michigan 48857-9792

Subject: Flint Municipal Water System

Dear Mr. Benton;

In your letter to then City Administrator Darnell Earley dated July 11, 2001, you alleged that some areas of the City of Flint municipal water system were "clearly deficient and need immediate attention". As Interim Utilities Director for Flint, I feel that substantial progress has been made in eliminating those deficiencies and request that you review the information presented in this letter in order to set the record straight.

Addressing those three items in the order in which they were presented in your letter, I submit the following:

1. Water Main Review Procedure. The plan review and permit issuance policy for the City of Flint has recently been revised to reflect the recent departmental reorganization. Work continues on the hydraulic model, but hydrant flow tests necessary for final calibration cannot be conducted until the weather cools off and illegal hydrant usage declines. The City and DLZ continue to hold regular monthly progress meetings for this project and final delivery and training in the operation of the model is expected by fall. It continues to be my recommendation that the City avoid private ownership of water mains except under very unusual circumstances.
2. Source Reliability. Efforts by the City of Flint continue on schedule for the funding approval and construction of Phase I, Segment 4 of the Water Plant Rehabilitation utilizing the DWRF. Should no unforeseen problems occur, a contract should be finalized and construction activities commence in October/ November of this year. Real-time chlorine residual monitoring of the water distribution system is in place and will now be reported in the Monthly Operation Reports. Future issues regarding plant operation remain to be resolved. Likewise, the provision of water to Genesee County remains to be negotiated. At this point in time, the City has not received any such formal requests from the County.
3. Distribution system.
   - The Cross Connection Control Program has been transferred to the Utilities Department. Glenn Thomas, who is certified by the State as a cross connection inspector, a licensed plumber and a certified mechanical trades

inspector, heads the program. Mr. Thomas works out of the Utilities Department office. He recently sent you a letter describing the City's program of inspections and enforcement. I trust that you will find it satisfactory.

- Unfortunately, I am unable to report any significant progress regarding improved record keeping for the distribution system valves and hydrants. It is our intention to add a data technician position to the Water Service Center staff whose role will be to maintain and update the hydraulic model. The long-range plan is to incorporate valve and hydrant records into the model and its associated database. We are also investigating the possibility of contracting for valve exercising and data collection services. Budget constraints make it unlikely, however, that any such contract will be entered into this year.
- The Utilities Department has a Capital Improvement Plan (CIP). This plan is divided into four parts, representing the four divisions of the Utilities Department: Water Plant, Water Distribution, Sewer Maintenance and Water Pollution Control Plant. These plans will be updated annually and used to determine budgets and future water and sewer rates.
- Although continuing understaffing of the Water Distribution staff exists, the Administration has approved filling numerous vacant positions over the course of the next few months. Provisional appointments have already been made to fill the Construction Equipment Operator and Water Meter Tech Foreman positions. Full staffing is expected to be in place by the end of the calendar year. The current budget includes over $200,000 for equipment for the Water Distribution Division. Lease/Purchase agreements are being explored to maximize the number of vehicles that can be put to work during the current fiscal year with financing to extend over three years.
- Water Rates. The current water rate ordinance has been modified to remove the 8% cap on water rate increases in any given year. Proposals for conducting a water and sewer rate study have been received and evaluated. A recommendation has been sent to City Council and they are expected to act later this month. It is anticipated that this rate study will result in water and sewer rates that are based upon the actual expenditures incurred to provide for operation and maintenance of the systems, debt retirement, capital improvement programs and depreciation of facilities and equipment.

For these reasons, I would request that the "Deficient" rating given to the City of Flint's municipal water supply system be revised and that a letter indicating that revision be sent to the City at your first convenience. Should you require any additional documentation regarding the progress noted in this letter, please feel free to contact me at (810) 787-6537.

Yours truly,

GRC Carlyon

WSSN: 2310

Dear Mr. Carlyon:

SUBJECT: City of Flint, Protocol for Water Main Approval

We have received a number of proposals from the city of Flint requesting a construction permit authorizing installation of water main in various locations. It was our understanding, based on our most recent discussion with you, that further water distribution and/or transmission main projects were on hold. Next, significant staffing changes within the various public works departments (Water Service Center, BSI, Water Treatment Plant, etc.) has resulted in a change in the city's protocol for reviewing and approving water main projects. A revised plan review procedure was recently submitted to us for review.

The revised plan review procedure continues to show two basic tracks and is satisfactory. However, some additional information concerning the city's review protocol is needed. Specifically, at what point in the city's review is the proposed project evaluated for conformance with the city's hydraulic network model. Who will be responsible for using the model to verify the hydraulic design for new projects?

Below is a list of projects submitted to us by the Transportation Department. These projects have been reviewed, and we are prepared to issue a construction permit following your approval and a response from the city pertaining to the items discussed above:

- 5th Avenue Water Main Replacement
- Pierson Road Water Main Replacement (MLK to Horton)
- Pierson Road Water Main Replacement (Fleming to Dupont)

Next, is a list of projects submitted to us by the Transportation Department in which our review reveals technical concerns, in addition to the issues discussed above, that need to be addressed prior to obtaining a construction permit:

- Ballenger Highway Water Main Replacement - inadequate number of isolation valves proposed at street intersections.

- Pierson Road Water Main Replacement (Dupont to MLK) – horizontal separation concerns from storm sewer from Station 19+58 to Glenn Avenue.
- MLK Water Main Replacement – cut and plug statements are needed for the tie-in mains at the intersections and the existing 12-inch main along MLK Avenue. There are also several vertical separation concerns with existing storm sewers in the vicinity of Damon Street, Gillespie Avenue, and Myrtle Avenue.

Finally, is the city intending to proceed with the six projects listed above or are they on hold?

If you have any questions regarding this issue or any other water related matter, please feel free to call me at the number listed below.

Sincerely,

Michael Prysby

City of Flint

Water Main Improvement Projects:

The City of Flint is proposing to commence with the construction of several new water main projects in the 2002, replacing water lines that are over 75 years old and to provide potable drinking water for service to existing and new developments/ land use and for fire protection. The projects in order of priority are:

Hamilton Avenue between Saginaw St. and James P. Cole Blvd
Ballenger Hwy between Augusta and the City Limits
Pierson Rd between Fleming Rd and Horton
Fifth Avenue between Prospect St and Chippewa
M.L. King Avenue between Pasadena and Flint Park Blvd
Fenton Rd between Hemphill Rd and Atherton Rd
East Court Street between Dort Hwy and Averill Ave.
Flushing Rd between Prospect and Ballenger Hwy
Third Ave between Chevrolet Ave and Saginaw Street.

If the community did apply for a loan, how large an SRF loan did the state determine potential grant recipients could afford to repay?	No No No No
2. How will the requested funds benefit low or moderate-income communities?	Provide reliable, continous potable drinking water supply. Existing water main is 75 yrs.old
3A. Will the requested funds be used for construction, not debt relief? 3B. Will this be a one-year request that will move a project into construction?	- Used for construction - To be used in current year.
4. What is the purpose of the project? Wastewater treatment or drinking water?	- Drinking water
5. What is the estimated average annual user fee as a percent of the estimated median annual income of households that will be served by the project if the community constructs the proposed project without the requested grant funds? with an SRF loan? with municipal funding at market rates?	Annual average cost of water per household is $456.00. Annual income is $10,000.00. %=4.6%.
6. What are the communitys plans for providing the expected 45% match?	Use of City Water Fund.
7. Does the project serve a broad public purpose or is it intended for a more limited (or private) purpose that could more appropriately be funded by a private party or local financing?	Serves to provide potable water to new housing and for fire fighting.
8. Does the project address an immediate need or is it predicated on future growth/development?	Existing water line is 75 yrs old. There is an immediate need.

Hamilton Ave. between N. Saginaw St & James P. Cole Pkwy.

- Replace 75 year old, deteriorating water line.
- Install a new 16 inch diameter water main and connections.
- Water main is important to serve existing and new land development.

Flint, Michigan 48505

Mr. Mark Horgan, P.E.
Genesee County Drain Commissioner
G-4610 Beecher Road
Flint, Michigan 48532

Dear Mr. Carlyon and Mr. Horgan:

SUBJECT: Richfield Township Water Main Extension
Transportation Service Center

We received a set of construction plans from the Michigan Department of Transportation (MDOT) for a water main extension along Potter Road that will serve a new MDOT building.

As we discussed, this project needs to be submitted to us through the Genesee County Drain Commissioner's office and be approved by the city of Flint prior to our issuance of a construction permit.

Finally, it is evident that there are issues pertaining to the location of the distribution main in proximity to the 72-inch transmission main along Potter Road. These issues need to be resolved and will likely require the establishment of a policy between Flint and Genesee County for water main extensions in this area. The policy should establish a procedure that will effectively address these issues for future projects.

If you have any questions regarding this or any other water-related matter, please don't hesitate to call me.

Sincerely,

Michael Prysby

July 11, 2001

Mr. Darnell Earley, City Administrator
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502

WSSN: 2310

Dear Mr. Earley:

SUBJECT: Flint Municipal Water System

Over the last several years, the Drinking Water and Radiological Protection Division (DWRPD), of the Michigan Department of Environmental Quality, has been working very closely with city of Flint officials regarding the municipal water system. The efforts have included inspections of waterworks facilities, meetings with staff from different city departments, and written correspondence documenting our findings, conclusions, and recommendations.

This letter is a summary of the status of three main areas regarding water system operation and maintenance. Significant improvements have been made in some areas, but other areas of water system operation are clearly deficient and need immediate attention.

1. Water Main Plan Review Procedure. A procedure has been implemented for the review and approval, by the city engineer, of new or replacement water mains. The plans are then forwarded to the DWRPD for issuance of the required construction permit. This procedure became necessary because projects were being initiated by different city departments or from private developers, and coordination was needed to assure compliance with city and state requirements.

   In addition to this new review procedure, the city's standard specifications for laying water mains have been submitted for review and comment. Another design standard that the city needs to establish is that of fire flow requirements. The city needs to determine the level of fire protection that will be provided to its customers. Some communities have different standards for specific service areas, such as residential, commercial, and industrial. The hydraulic network model, to verify that a particular water main design will meet the city fire flow requirements, also needs to be completed. These are issues that the city needs to address so that all proposed projects meet city standards.

Another related issue is that of ownership of water mains. The city has previously allowed the installation of privately owned water lines. This is an issue that we have reviewed with staff without resolution. It is generally not in the city's best interest to allow privately owned water lines, but there are exceptions. This issue needs further discussion and perhaps a city policy.

2. Source Reliability. The rehabilitation of the water treatment plant is an extremely important project, and the city is to be commended for its progress. We have just recently issued the construction permit for the third segment of the proposed five-segment project. The plant will provide a back-up source of drinking water in the event of a failure of the primary supply pipeline.

   Other improvements at the plant have already improved operation of the overall system by upgrading the monitoring, and control of flows and pressures around the system.

   Future issues regarding the water plant include when and at what rate will the plant operate, and will it provide water to Genesee County. An engineering study of the pumping stations is also planned, but is on temporary hold due to the amount of time and effort required of staff for the plant rehabilitation project.

3. Distribution System. Despite progress in the first two areas, there are severe deficiencies within the distribution system facilities and operation. In March of 2000, we sent the city a complete evaluation of the distribution system called a "Sanitary Survey." In this document, we noted several areas where there were severe problems. We have met with staff on several subsequent occasions to review the issues, but adequate progress has not been made. The following is a list of the most serious concerns:

- Cross Connection Control Program. The program for controlling the potential for backflow of contaminants to the distribution system has essentially been discontinued. This represents a clear threat to the public health of your customers and must be addressed as soon as possible. The city's ordinance, program, and designated agent all need to be reviewed and updated.

- The records for the distribution system valves, hydrants, and meters are in need of attention. The valve records are in the worst condition with the city having records on only 1,500 valves out of a total of 8,000 to 10,000 valves in the system.

- The city does not have a "Capital Improvement Plan"(CIP). All well run municipal utilities need an on-going CIP to address infrastructure replacement or rehabilitation. The city experiences 300 – 600 water main breaks per year but there is no plan to replace aging, deteriorating water mains.

- Staffing and equipment needs at the Water Distribution Division need to be reviewed. The city cannot address its backlog of work without adequate personnel and quality equipment.

- Water Rates. The deficiencies noted pose an enormous threat to the city and its future. We understand that the city is going through financial difficulties, but the condition of the distribution system cannot be allowed to deteriorate further. A rate study should be performed without delay, and water rates raised to ensure that there are adequate dollars to run the system and address the problems.

Based on these problems, the city's distribution system has been given a **"Deficient"** rating. Once you have reviewed this letter and have had a chance to discuss the issues with staff, we would appreciate an opportunity to meet with you. If you have any questions, please call me.

MORRICE MI 48857-9792

June 20, 2001

Mr. Hans Kuhlmann, P.E., Deputy Director/City Engineer WSSN: 2310
Department of Public Works & Utilities
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502

Dear Mr. Kuhlmann:

SUBJECT: Water Main Plan Review Policy

This will confirm our meeting of June 19, 2001, and our discussion of the comments and suggestions raised in our March 28, 2001, letter to you regarding this issue.

You indicated that some office names and/or titles would be included in the policy, and that the number of sets of plans to be submitted would also be clarified. In addition, the policy would be put on city letterhead and distributed to appropriate city departments, as well as local consultants.

Adherence to the plan review policy is required. Plans for water main extensions that are sent directly to us without the required approval by your office will be returned to the consultant.

Other important issues related to the installation of new water mains were also discussed and are summarized as follows:

1. The city needs to submit a set of standard water main specifications for review and approval. It is common for construction plans to note that all work shall comply with city standard specifications, however, we do not have your specifications on file. If the city needs to update its standard specifications, we would review a draft and offer comments if requested. It is important to keep city specs current due to changes in water main materials, construction techniques, revisions to American Water Works Standards, etc. For example, ductile iron pipe is now available as "standard pressure class" or "special thickness class," and city specs should reflect whether both are acceptable or if one type is required.

2. The city needs to compile other water main design standards as well. For instance, issues such as minimum pipe diameter (which we just received) and fire flow requirements need to be established. In most situations, fire flow requirements dictate hydraulic design. Therefore, we need to know the community's design standards. The level of fire protection to be provided typically varies from residential to commercial or industrial areas, and represents a significant cost issue.

3. The status of the city's hydraulic network model needs to be clarified. Which city office will be using the model to verify the hydraulic design for new projects? The model outputs should be available for review and discussion for new or replacement water mains. A

functional hydraulic network model is an extremely valuable tool for water system engineers, operators, and managers. We would like to know who at the city will be responsible for the model use and upkeep.

4. The city's lead service replacement policy was discussed. It was learned that when lead services are encountered, the city is replacing the city owned portion of the line from the main to the curb stop with copper. The portion of the service line from the curb stop to the building is the responsibility of the owner. The preparation of an official notification from the city to the owner regarding the work the city performed and recommendations for the owner was then discussed. This notice would also include the names of contractors approved by the city for service line installation. We would appreciate receiving confirmation of the city's policy and procedures for lead service lines.

5. The issue of customer site piping versus water main was briefly reviewed. Copies of our policy regarding this issue were left with you for your use. This issue needs to be addressed, but should be the subject of another meeting due to its complexity. However, as I indicated, if the city's degree of control over the privately owned lines is satisfactory, it would be possible to consider the lines to be water main. It should be noted again that allowing privately owned water lines or customer site piping is not in the city's best interest.

We look forward to receiving a copy of the final plan review policy, and to receive all future plans from your office with a cover letter requesting that a permit be issued. The cover letter will also verify that the plans are acceptable to the Water Distribution Division and meet all applicable city standards and specifications. As we noted previously, our typical review time is generally less than 10 days for most water main projects.

Regarding the other items, we also look forward to hearing from you as these items are prepared.

Sincerely,

Timothy A. Benton, P.E.

Department of Public Works
City of Flint
1101 South Saginaw Street
Flint, Michigan 48502

WSSN: 2310

Dear Mr. Kuhlmann:

SUBJECT: Water Main Plan Review Procedure

We have reviewed the draft of this procedure that you submitted and have some comments, suggestions, or questions.

Overall the procedure appears logical and straightforward. It might be helpful to include some contact names, phone numbers and possibly some addresses. The number of sets of plans to be submitted to us (Part 1G and Part 2K) should be specified. In general, at least two sets of plans are needed for our review. We retain one approved set for our files and generally send the community an approved set for their files. If the Water Service Center or another party wants an approved set we can easily accommodate that need.

Similarly, in Part 2A, how many sets of plans does the city require to be submitted to BSI? In addition, does BSI want us to send them a copy of the DEQ construction permit for Part 2 and/or Part 1 projects?

It might be helpful to include a Part 3 for city approval of Genesee county projects. At present, we receive the plans directly from the county and generally wait to receive an approval letter from the water plant supervisor prior to issuing a construction permit. We assume that one set of plans has been submitted by Genesee County directly to the water plant supervisor at the Dort Highway location. We do not copy the city with our permits. This procedure seems to working satisfactorily.

After this procedure is finalized it might be useful to put it on city letterhead and distribute it to the different departments charged with project initiation, design, or review and approval.

It should also be noted that the permitting process should be completed before projects go out for bid. This most important for any project that will be installed by private contractors.

In a related issue, we have a number of questions concerning the actual design of water main projects.

1. Does the city have current water main specifications? We do not have a set on file here and would appreciate a copy for our use.
2. Does the city have current design standards for minimum main size, fire flow requirements, ownership, etc.? Is the city's hydraulic network model able to be used to design new water mains?
3. When replacing water mains, what is the city's policy on lead service line replacement?
4. How many city departments actually initiate or design projects(Part 1A)?
5. Is there a plan or process for determining which water mains are in need of replacement? We realize that critical road projects, CSO problems, re-development projects, etc., often dictate water main replacement. Nevertheless, existing water mains need to be evaluated based on break history, available flows and pressure; water quality, and reliability of service. There is undoubtedly a backlog of projects that need to be addressed.

Regarding future distribution system projects and according to your draft procedure, we will be receiving plans from your office with a cover letter requesting that a permit be issued. The cover letter will verify that the plans are also acceptable to the Water Distribution Division and meet all applicable city standards and specifications. Our typical review time is less than 10 days for most standard water main projects assuming that the applicable design standards are met.

As we discussed at our meeting on February 20, 2001, it would be most helpful for us to meet more frequently to improve communication. I would like to meet with you the last week in April or the first week in May to discuss the items in this letter as well as the reponses we received from you concerning the sanitary survey.

If you have any questions or concerns, please contact me.

February 23, 2001

Mr. Hans Kuhlmann, P.E., Acting Director
Department of Public Works
City of Flint
1101 S. Saginaw Street
Flint, Michigan 48502

WSSN: 2310

Dear Mr. Kuhlmann:

Subject: Water System Construction Permits

Please find two enclosed Water System Construction Permits for the water main replacement in Martin Luther King Boulevard and water main relocation in main in Leith Street and St. John Boulevard ("UPF" project). Both of these projects were recently brought to our attention after construction had commenced. Please note that Water System Construction Permits are required prior to water main installations. Part 13 of Michigan's Safe Drinking Water Act, 1976 PA, Act 399, as amended, addresses the requirement for permits.

> R 325.1004 - Sec.4 (3) states in part - Before commencing the construction of a waterworks system or an alteration, addition, or improvement to a system, a supplier of water shall submit the plans and specifications for the improvements to the department and secure from the department a permit for construction of the same...

In addition, a third water main project, the U of M-Flint Professional Studies Classroom Building, was completed without a Water System Construction Permit. Upon review of this project, it was determined that the water main as shown is "customer site piping" as defined by the safe drinking water act. Furthermore, the plans depict two connections to the Flint system and a private 8-inch main owned by U of M-Flint. This design creates a "flow through" situation which is expressly prohibited by the safe drinking water act. In general, private ownership of water mains is strongly discouraged by the department. The plans for the U of M-Flint project have been stamped "Accepted for Record" and will be retained for our files. A construction permit will not be issued for this project.

Based on our meeting on February 20, 2001, it is clear that there are several customer site piping situations within the City of Flint's distribution system. It is also apparent that, although the City of Flint does not "own" this piping, it still maintains some degree of control, and may perform or monitor the repairs of privately owned mains. As we

discussed during our meeting, if the full extent of the city's requirements

for privately owned mains can be ascertained, and the degree of city control is judged to be satisfactory, a flow through design may be allowable.

Regarding future distribution system projects, plans should be submitted to this office with a cover letter from the Director of Public Works requesting that a permit be issued. The cover letter should verify that the plans are also acceptable to the Water Distribution Division and meet all applicable city standards and specifications. The typical review time for our department is less than 10 days assuming that the applicable design standards are met.

We would also appreciate receiving a description or protocol from you that outlines the process whereby a proposed project moves through city government. It would be helpful for us to know where in this process the DEQ permit requirements are addressed. Also, I have included a copy of our division policy regarding construction permits and customer site piping for your use.

Another major issue discussed at our meeting was the city's lack of response to our Sanitary Survey of the Flint distribution system. We understand that our evaluation of the system is a topic new to you and that it will take some time for you to review the document and prepare a response. We look forward to hearing from you.

Should you have any questions or concerns, please contact me.

Dear Mr. Sargent:

SUBJECT: Flint Sanitary Survey Items

In a June 2, 2000 letter, we requested comments from you addressing the items discussed in the Water Distribution System Sanitary Survey. It is our understanding that Robert Carlyon and Roger Clapp would prepare comments on their specific items and forward them to us through you. Since that time, we have not heard from you.

This letter also confirms our meeting with Jacob Hawkins from BSI on June 16, 2000, to discuss Flint's Cross Connection Control Program (CCCP). Our June 22, 2000, letter (copy enclosed) confirmed this meeting. Improvements that are needed with the CCCP were noted and a summary detailing (proposing) what will be accomplished over the next two years was requested.

Please provide us, at your earliest convenience, your response to the Sanitary Survey items that were discussed in our June 1, 2000, meeting. As we discussed, utility operation needs improvement in several areas. The amount of progress made will play a key role in determining whether Flint's overall water system rating improves or declines.

Please call me if you have any questions regarding this or any other water related matter.

Sincerely,

Michael Prysby

WSSN: 2310

Dear Mr. Hawkins:

SUBJECT: Flint Cross Connection Control Program

This letter confirms our meeting on June 16, 2000, with you and Glenn Thomas. The purpose of the meeting was to discuss improvements that are needed with the city's cross connection control program (CCCP). The majority of program improvements that are needed focus on inspection schedules, record keeping, and overall program tracking. An outline of suggested CCCP content was left with you. This outline is again summarized below in the same order.

1. A Cross Connection Control Program needs to be prepared and submitted to our office for review and approval. The program can basically follow the model program outlined in Appendix C of our rules manual. The program should also specify the breakdown of high, moderate, and low priority accounts, and an annual inspection schedule based on designated priorities.

2. Prepare or reconcile your list of accounts that are eligible for routine inspections. This list must include all industrial, commercial, governmental, institutional, and "other" types of non residential accounts. This list should be prioritized according to the degree of risk (high, moderate, low) that each establishment poses. Risk level should be based on both the **potential** for backflow and the degree of **threat or danger** that the backflow poses. This may need to be adjusted after completing inspections at the various locations.

3. A routine inspection schedule needs to be prepared and the frequency would be based on the prioritized list of accounts. As we discussed, high, moderate, and low priority accounts should be inspected at least 1/year, once every 2-3 years, and once every 3-5 years respectively.

4. Inspection records need to be maintained for each account as was noted during our visit. Records may need to be established for some of the establishments. It may be worthwhile to utilize our reporting forms (Appendix D) when updating or adding to your inspection records.

5. Records of corrective action should also be maintained. It was noted that the fines for failure to address cited violations needs to be adjusted. We would agree that the fines need to be increased and would call for a revision of the Cross Connection Control Ordinance (Ordinance No. 3267). Please send us a copy of your draft ordinance for our review prior to being adopted.

6. Maintain an active on-going RPZ device testing program each year. The total number of RPZs tested each year needs to be noted on the annual report. Testing of other types of backflow preventers will eventually be required. We will keep you informed as to the status of this new requirement.

7. Provide continued training in cross connection control in order to conduct the vital program elements effectively. We would suggest sending your operators to our Cross Connection Control Seminar in Lansing. Also, there are other organizations including AWWA, Rural Water, and Midwest Backflow Prevention that offer further cross connection control training. Finally, it may also be worthwhile to retain a consultant who can also offer program training assistance. Additional information listing various training courses in cross connection is enclosed with this letter.

Finally, it appears, based on our discussion, that BSI intends to update the cross connection control program. We realize that a program of this magnitude will take a lot of time, effort, and personnel towards improving the CCCP. It was noted that an additional one or two operators may be needed in order to adequately implement this program. We would encourage the city to review staffing needs with BSI and authorize the additional workforce needed. Finally, we would like to receive a summary detailing (proposing) what will be done in 2000 and 2001 towards improving this program. We will review this and discuss some of the various aspects, as needed, in more detail.

We appreciate your time and assistance during the visit. Please don't hesitate to call me if you have any questions regarding this or any other water related matter.

Sincerely,

Michael Prysby

Dear Mr. Sargent:

SUBJECT: Sanitary Survey Review

Thank you for the opportunity to discuss the issues raised as part of our Sanitary Survey of the Flint water distribution system. Although we did not have as much time as we would have liked to thoroughly review all the items, it was agreed that Bob Carlyon and Roger Clapp would prepare comments on their specific items and forward them to us through you. In addition, we will contact Jacob Hawkins to set up a meeting to discuss the cross connection program in more detail.

As we noted, the city distribution system has been given an overall "Marginal" rating. However, there are a couple areas of utility operation that are clearly deficient and that need significant attention. Many of the items will take time to correct but a commitment must be made and progress must be forthcoming. The city's efforts over the next 12 to 24 months will determine if the overall system rating improves or declines.

If at any time questions arise concerning the survey or any water system issue, please call me at the number below or Mike Prysby at 517-625-4670.

Sincerely,

Timothy A. Benton, P.E.

Dear Mr. Sargent:

SUBJECT: Sanitary Survey
City of Flint Water Distribution System

Enclosed is a copy of the city of Flint's Water Distribution System Sanitary Survey completed by this department. This report is being submitted for your review and comment.

Your attention should be directed to pages 23 through 33 which details our observations, conclusions, and recommendations. Also, page 34 provides a brief summary of the individual items that need to be addressed and references the pages in the report where those items are discussed.

Items # 1 and 2 pertain to Flint's storage and booster pumping stations. This discusses the need to develop and follow through on a proposed pumping station Master Plan.

Item #3 discusses the need to develop a Capital Improvements Program that addresses both transmission and distribution system needs.

Item #4 discusses the need to establish an adequate operation and maintenance program for hydrants and valves.

Item #5 discusses additional operational details that need to be included as part of Flint's monthly operation reporting.

Items #6, 8, 9, and 10 discuss the various water system programs and plans. This includes improvements needed with the Cross Connection Control Program and preparation of an adequate Contingency Plan. Updating the water system General Plan and a continuation of the Lead and Copper Program are also discussed.

Item #7 discusses the need to formalize the city's water main extension approval process.

Item #11 discusses the need and benefits of promoting operator certification and training.

The items vary in priority and are listed without ranking.

We wish to thank your staff for their time and assistance given during the survey and preparation of the report. We will be contacting you to arrange a time to meet and discuss the contents of this report.

Sincerely,

Michael F. Prysby, P.E., District Engineer

Dear Mr. Carlyon:

SUBJECT: Bacteriological Monitoring and Reporting

This letter confirms my visit on January 20, 2000 with you, David Jansen, and Cindy Butcher. The purpose of the visit was to discuss sample results obtained from the city distribution system in December that were positive for total coliform bacteria. Tim Benton from our office also participated in the discussion.

Routine and repeat distribution system bacteriological monitoring during the month of December produced a total of eight results that were positive for total coliform. Since a total of 155 distribution system samples were noted on the Monthly Operation Report (MOR), the number of total coliform positive results exceeds five percent of the total number of samples collected and would constitute a total coliform Maximum Contaminant Level (MCL) violation. A closer review of Flint's bacteriological monitoring program revealed that distribution system monitoring is routinely conducted at Control Station #2, however, they are not reported as distribution samples. Although monitoring at Control Station #2 was never reported on the MOR as distribution system samples, we agree with the concept of adding Control Station #2 samples to the total number of distribution samples that are collected. This will result in a total of 279 distribution system samples for the month of December with nine being positive for total coliform. Since this is less than five percent of the total, an MCL violation did not occur. As we discussed, the monitoring results from the Control Station need to be reported on the distribution system page of the Monthly Operation Report (MOR). Finally, we will update our data tracking system to include Control Station #2 sampling as distribution system samples for the entire 1999 calendar year.

Next, revisions with the city's bacteriological Sampling Site Plan are underway. Specifically, there remains the difficulty of maintaining consistency with some of the repeat sampling locations on the city's north side. Plans are underway to install Eclipse monitoring stations at some of these locations. These changes will be noted on the updated Sampling Site Plan.

Finally, samples are collected from 14 locations out of which three are from city owned facilities. The concentration of sampling locations, however, may be slightly overdone on the city's west side. Although there is no requirement within the Michigan Safe Drinking Water Act that establishes a minimum number of sampling locations, we would suggest that a minimum of ten routine distribution system sampling locations be utilized.

Please send us a copy of your revised Sampling Site plan after the revisions are completed.

If you have any questions regarding this or any other water related matter, feel free to call me.

Sincerely,

Michael Prysby

Dear Mr. Sargent:

SUBJECT: Shiloh Commons Water Main Installation

This letter is to acknowledge receipt of the revised set of plans for the Shiloh Commons water main installation that was prepared by GM Engineer and Associates and submitted to this office by you. It is our understanding that the water main for this project is already installed.

As a reminder, Section 4 of Public Act 399, 1976, requires that the water supplier obtain a permit prior to the installation or construction of any water system improvement. In addition, plans submitted for our review need to be signed and sealed by a Licensed Professional Engineer.

As such, the plans have been stamped "Accepted for Record" and will be kept for our files. A water system construction permit will not be issued for this project.

Should you have any concerns or questions, please contact me at the number below.

Sincerely,

Michael Prysby

SUBJECT: Water System Construction Permit Application
General Motors Infrastructure Improvements - Phase 2

Dear Mr. Sargent:

As discussed this morning during a telephone conversation with Mr. Jim Watling, of this office, a Water System Construction Permit cannot be issued for the above project until we receive written correspondence from the city of Flint that the project plans and specifications have been reviewed and approved. Part 13 of Michigan's Safe Drinking Water Act, 1976 PA 399, states the following:

> R 325.11302 – Rule 1302 (1). For Type I water supplies, before the construction or alteration of any waterworks system, or a portion thereof, plans and specifications shall be submitted to the department by the supplier of water or designated agent for review, approval, and issuance of a permit.

It is our intent to expeditiously issue permits for water main construction. However, we need to be sure the appropriate city official(s) have reviewed and approved the final proposed plans prior to issuance of a permit. If someone other than you will be issuing approval on the city's behalf, we should be notified accordingly.

Should you have any questions or concerns, please don't hesitate to contact me.

Sincerely,

Timothy A. Benton, P.E.

Flint, Michigan 48506

Dear Mr. Clapp:

SUBJECT: Flint Water System

This letter confirms our meeting at the Flint Water Treatment Plant on January 27, 1999. The purpose of the meeting was to discuss the completion of the 1999 Infrastructure Needs Survey. Some time was also spent discussing submittal and review of construction plans for water main extensions. Specific items are discussed below in more detail:

1. Items listed on the Infrastructure Needs Survey were discussed with you and Bob Carylon. Some modifications were made in main sizes and the number of valves. Also, the breakdown of costs for several projects associated with serving Genesee County will need to be clarified. Arrangements will be made to meet with the county and the city to resolve the remaining items.

2. As we discussed, the needs survey is very similar to our Distribution System Sanitary Survey. The survey will cover the major aspects of Flint's distribution system including the condition of the distribution and transmission piping, pumping stations, and storage facilities. The survey also includes a check on the status of the operator certification program, water quality, and the utility's record keeping and monitoring programs. Finally, the Cross Connection Control Program (handled by another city department) will also be evaluated. The findings of the survey and recommendations that follow will help provide additional basis to support Drinking Water Revolving Loan (DWRF) projects and the Infrastructure Needs Survey.

3. Our department has recently received requests for permits for water main extensions. However, there was no indication that the city has reviewed and approved these plans. A plan review protocol needs to be developed. The typical procedure would require consultants to submit plans to the city for review and approval. Plans approved by the city would then be sent to our office for our review and issuance of a state construction permit. Also, we should have a copy of the city's current standard specifications. Finally, it appears that a water main project has commenced without the issuance of a construction permit as required by the Michigan Safe Drinking Water Act. Arrangements will be made to meet with you to discuss this project and the entire permitting process in more detail.

A water system survey form was left with you during our meeting. Arrangements will be made to work with you over the next several months to complete this document. I am looking forward to working with you and other staff from the Water Service Center towards completing the survey.

If you have any questions, please do not hesitate to call me.

STATE OF MICHIGAN CONTRACT NO. 271N3200089

CITY OF FLINT WATER SUPPLY ASSESSMENT

At the request of the Treasurer, Tucker, Young, Jackson, Tull, Inc. (TYJT) makes the following recommendation to the Department of Treasury concerning Flint's water supply alternatives. Based on the financial analysis performed of the various options presented by DWSD to continue treated water service to Flint compared to Flint being supplied by the new KWA untreated water system, TYJT believes that several of the options presented by DWSD are lower in cost currently and over the long run than the one offered by KWA. TYJT also believes that DWSD's most recent offer (subsequent to the submittal of our report) to build a smaller parallel water main from Imlay to Flint, funded by the entire DWSD base of customers, is the best solution offering the least cost alternative and the required redundancy by MDEQ.

Furthermore, since a majority of the KWA system has not been designed and none of the system has been constructed, there is an additional risk that the cost of the KWA system may actually be higher than estimated due to potential construction delays and unforeseen conditions. This risk to Flint could be substantial since the city is responsible for 30 percent of the KWA design and construction costs while still having to purchase water from DWSD during the construction period.

Finally, there are other issues that were identified in our report that may result in risks to Flint if it were to join KWA that should be considered by the Treasury in determining how Flint's potable water should be supplied. These issues are related to redundancy and reliability, other items affecting cost, and Flint's desire to control its own destiny related to its water supply. These are described further below.

- DWSD's supply to Flint is via a 72-inch water main from Imlay City. This main also supplies Imlay City, Mayfield and the Greater Lapeer County Utilities Authority (GLCUA). The volume of water contained within the 72-inch main is approximately 30 million gallons. If Genesee and Flint move to KWA then the three remaining communities' consumption would most likely not be large enough to maintain fresh water in DWSD's pipeline (due to loss of chlorine residual). DWSD may consider shutting down the 72-inch line completely due to the water quality concerns, which would then create an additional burden for Imlay, Mayfield and GLCUA to finance treated water supplies.
- The KWA supply option is counter to the Treasury's Competitive Grant Assistance Program (Formerly EVIP Grant). This program has been put in place to allow for communities to consolidate their services and save money. Two existing customers of DWSD (Flint and Genesee County) along with the potential of others customers (GLCUA, Mayfield, Imlay City) separating from another water system is in contradiction to the program.
- There is a concern over the ability of smaller systems (KWA) over larger systems (DWSD) to pay for future unfunded mandates and regulations. Obviously, identifying regulation requirements over 30 years is hard to determine. However, it is widely accepted that a large system has greater ability to respond to unfunded mandates because the cost can be distributed over a large customer base.
- Although Flint will be responsible for 30 percent of the construction cost, they will only have a minority vote on the KWA board. Furthermore, there are other communities (Lapeer County, the City of Lapeer, and Sanilac County) that sit on the board and vote. However, they are not purchasing water nor contributing to the construction costs. Their position on the KWA Board will not provide them an ability to "control their own destiny," as they have stated to the Treasury.

Summary of FY 2013-14 DWSD Cost Allocations to Flint Under Various Scenarios

Subject: RE: Schedule 2 plants

4/1/15 Population chg's per census

I think we can safely place them in Schedule 2. If that schedule results in their monitoring not being completed before they connect to the Authority's pipeline, we should ask them to complete the monitoring so both we and they know their LT2 Bin Classification and what level of treatment is appropriate should they ever need to rely upon the river again.

As for the Needs Survey, the 2013 Census Bureau estimate could have justified them being excluded from the category of systems serving greater than 100,000 that all have to submit a survey. However, since we used a population of over 102,000 for their 2015 Annual PWS fee and the city paid it, we can assume the population EPA and Cadmus were given on the date they froze the data for the Needs Survey was over 100,000. Next survey, the city will have to be randomly selected to be included unless they reverse the population decline by 2018-19.

Subject: RE: Schedule 2 plants

Here is the timeline I have for Flint population info.

3/2013 Sanitary survey completed and mailed based on 2010 Census population of 102,434

7/2013 Census Bureau publishes 2013 census estimate for Flint of 99,763

11/2014 LT2 schedule developed with Flint Schedule 2 based on latest (2013) census estimate.
Estimate validated by City DPW staff based on vacated service accounts.

Based on the Needs Survey emails from EPA it would appear that the Need Survey populations were validated by the states earlier than November 15, 2014, which is prior to this population change.

Before you change the population in SDWIS, we need to discuss this with Richard. He is concerned about some other ramifications by lowering their population below 100k for some other programs, like the Needs Survey.

Pat,

Your note serves as a reminder for me to confirm Flint's population (<100,000). I requested the city to provide us with the most recent number of residential accounts ...if which they have responded. Flint's most recent estimate of residential accounts shows further loss of customer base...and is below 100K. I will tally up the numbers, compare against their most recent Sanitary Survey and provide an updated population estimate for Adam to enter into SDWIS.

Subject: Schedule 2 plants

Hi All,

According to the population figures in SDWIS, below is a list of Schedule 2 water plants that will have to conduct a second round of Crypto, E. coli and turbidity sampling from their raw water source(s) starting in October, 2015. This monitoring is required by the Long Term 2 Enhanced Surface Water Treatment Rule and Act 399. As a reminder, a Schedule 2 water plant serves 50,000 to 99,999 people OR belongs to a Combined Distribution System in which the largest system serves 50,000 to 99,999.

The plan is to forward to the appropriate district engineers a sample letter and Monitoring Plan template that they in turn will have to mail to the plants. The letter explains the source water sampling requirements while also reminding them that the monitoring plans have to completed/submitted to the district office's by July 1st.

Please look at the below list and let me know if any plants meeting the Schedule 2 definition are missing or need to be added.

Schedule 2 Plants

- All plants receiving raw water from the Saginaw Midland pipeline: Au Gres, Linwood, Omer, Saginaw, Sims-Whitney, Standish, Midland
- Flint
- Wyoming

EM Press Briefing For Week of 5/01/2013

KWA vs. DWSD Facts & Figures

- The Karegnondi Water Authority (KWA) is regional water authority that would provide raw water to Flint and Genesee County via a direct pipeline.
- This offer has more risk involved than previous proposals. KWA would be responsible for between 20% and 100% of the repair costs on the pipeline and related assets from Port Huron
- The numbers in the offer do not make sense. DWSD indicates savings of over $900 million while KWA's total cost over 30 years is less than $650 million.
- Offer is based on very little capital improvements, no repairs and a 4.7% annual increase over the life of the contract.
- There are no rate guarantees after the first year for capital, O & M or consumption.
- KWA would be responsible for redundancy at a cost of $94.68 million per DWSD's estimate.
- Does not guarantee a rate structure if system regionalizes or DWSD regionalizes, or Detroit enters bankruptcy.
- Flint and Genesee County could have a connected waste/water system that serves all or part of five counties.
- The potential for further consolidation of services between the city and the county i.e...water, wastewater, 911, etc,
- This partnership will give Flint ownership of the city's own water supply system with real representation on its board of directors, making all treatment and delivery system decisions.
- Flint's participation allows the city to utilize its own water treatment facility that it has invested $50 million into and only currently exercises four weeks per year.
- The investment gives Flint and Genesee County a new pipeline with a life expectancy of 75 years, as well as a 2nd product, untreated water. Under DWSD we would have no ownership after the end of the contract, and a new pipeline would still need to be built.

- A 30 year contract with DWSD keeps Flint and Genesee County on a system that is 48 years old with a design life of 75 years. There will be necessary major investments or replacement costs that are not accounted for in this DWSD proposal.
- KWA guarantees its capitol rate for 25 years. The capitol rate is 90 % of the total costs.
- The commodity charge of $1.30 per MCF is mainly driven by energy costs. The whole operation will employ 5-7 people.
- A thirty year contract with DWSD will lock Flint into hundreds of employees, labor costs and legacy costs.
- The combination of low financing, labor and material make this the optimal time for this investment. At our meeting with the governor on April 19th Detroit acknowledged a second pipeline had to be built.
- KWA could be used as a backup emergency supply for the existing 48 year old pipeline.
- It brings a total economic package to our community i.e. We have the I-69 corridor, I-75 interchange, the rail system connected to Port Huron, and one of the busiest airports in the state. Owning our own water supply completes that package and keeps $25 million in our community.
- Mr. Fausone's continued insistence on a 12 month timeline to calculate the termination fees leaves a question mark on the costs.

Construction Costs

- Rowe/AECOM/J & H $272,000,000
- TYJT $357,000,000

  Include: 10% bond coverage (dispelled)

  30% additional engineering (dispelled)

  Back-up power (dispelled)

- DWSD Starts at: $357,000,000 and adds:

  $134,360,000 for bond sizing

  $11,074,500 for bond sale cost

  For a total of $503,274,500

  Plus need to collect $6,984,000 per year extra for bond coverage 20%)

Now KWA needs:

20% bond coverage

30% additional engineering

38% bond sizing

The KWA dispelled TYJT's numbers; now DWSD starts with those numbers and adds more. They add the same costs to Flint and GCDC construction costs (baseline figures and assumptions – KWA).

Add notes for 8/20/13 WTP meeting

Proposed Scope of Upgrades to Flint WTP

1. Introduction

The City of Flint plans to utilize their existing WTP to provide water on a continuous basis. The city plans to treat water from the Flint River until construction of the proposed KWA supply is complete and the WTP can then be used to treat water from Lake Huron. An evaluation of the WTP to provide treatment of water from both sources is in process to define the scope of upgrades needed to provide reliable service. In addition to the different treatment requirements of each source, the WTP has not been operated on a continuous basis for 40+ years so facilities are also being evaluated to identify equipment which should be replaced because of its age, condition, or obsolescence.

2. Preliminary Scope of Work

Based on the WTP evaluation, the following scope of proposed upgrades has been developed. This summary is preliminary, provided for review and comment by interested parties. Comments received will be used to finalize the scope of work to be implemented at the Flint WTP.

The proposed upgrades have been categorized into two phases. Phase 1 is work that will be completed as soon as practical so that the WTP can be utilized to treat water from the river in 2014. Phase 2 work is needed to provide long-term service with the proposed KWA Lake Huron water source. Phase 2 work will be completed in 2015 to 2016.

Work is proposed to be contracted except where noted "by city" the work is planned to be completed by City staff.

Item 1 – Chemical Systems / Ozone

Additional storage of nitrogen and oxygen will be provided for redundancy and 30 day capacity.

Existing ozone units will be serviced to prepare for continuous operation.

New alternative coagulant chemical feed system will be added for treatment of raw water from Lake Huron.

Phase 1	Phase 2
Oxygen and nitrogen storage	New coagulant feed system
Service existing ozone system (by city)	

need feed system or new coag?

Item 2 – Electrical

The WTP presently uses 2400V as primary power. Power feeders and switchgear are rated at 5kV. Upgrading the primary power to 4160V will enable existing power feeders to provide twice the power and eliminate the need to install new feeder circuits throughout the WTP.

The current substation has two 2.5 MVA transformers running in parallel for a total capacity of 5 MVA. The transformers are obsolete. It is planned that the transformers and conductors to the WTP will be replaced to provide two independent power sources for redundancy. The existing on-site backup power generators are obsolete and inoperable. Since two independent power sources will be provided to the WTP, replacement of the generators is not proposed.

Electrical switch gear and equipment at Pump Station 4 will be replaced.

If filter presses (or other equipment) are utilized for dewatering of softening sludge, a new power feed will be required to the equipment.

Electrical switch gear and equipment at Plant 2 will be replaced.

Phase 1	Phase 2
Upgrade existing substation and power supply	Upgrade power system at Plant 2
Upgrade facilities at Pump Station 4	
Power to filter presses? TBD	

Item 3 – Mid-Point Chlorination

Mid-point chlorination facilities are proposed, including the following principal components:

- Feeders, scales, monitors
- Piping, valves, and controls
- Scrubber
- Ton Containers
-

Phase 1	Phase 2
Mid-point chlorination	

Item 4 – Security Measures

Add three additional security cameras to monitor the following areas:

- Chlorine storage area
- Oxygen and Nitrogen storage area
- East side of WTP property

Phase 1	Phase 2
Additional security cameras (by City)	

Item 5 – Low and High Service Pump Station No. 4

As a result of decreased demands, pumps at Pump Station No. 4 are "over-sized" and do not efficiently operate. Some of the pumps experience vibrations in the shafts and steady bearings. The existing pump station will be rehabilitated to replace "over-sized" pumps and obsolete equipment and provide needed maintenance. Proposed work includes:

- 25 mgd Low Service Pump No. 4 – upgrade motor to inverter duty, rehabilitate pump and piping, install new valve, and install new VFD
- 15 mdg Low Service Pump No. 6 – rehabilitate pump shaft and bearings
- Install two new High Service Pumps (15 mgd @190 feet TH, vertically mounted pumps with 800 HP 2400/4160 V inverter duty motors, with 20 feet of shaft and steady bearings)
- Replacement of existing piping, valves, supports, and bearings
- New intermediate platforms, ladders, & stairs
- New ventilation (for exhausting heat from VFD's)
- Install two medium voltage VFD units
- Demolition of existing equipment to accommodate new equipment

Rehabilitation of Pump Station No. 4 is planned to be completed in two phases. A new high service pump and a new low lift pump will be installed initially to provide efficient service during the period when water from the Flint River is treated. Additional high service and low lift pumps will be installed later to provide long-term reliable, efficient service.

Phase 1	Phase 2
Rehabilitate Pump 6 shaft and bearings (by City)	Rehabilitate 25 mgd Low Service Pump No. 4, new motor, new valve, new VFD
New High Service Pump No. 1	New High Service Pump No. 2
Install VFD for Pump No. 1	Install VFD for Pump No. 2
Provide ventilation for Pump No. 1	Provide ventilation for Pump No. 2
Demolition of existing equipment	Demolition of existing equipment

4 appeal angle in sump ? Double check

Item 6 – Filter Transfer Station

Recent changes in regulations, enhanced CT is required. Additional CT can be provided by including the volume of the Dort Reservoir in the process train. However, because of its elevation with respect to other treatment processes, pumping will be required to utilize the reservoir. The proposed pumping facility will provide for the following:

- Three 12 mgd @ 40 ft TH vertical turbine pumps with 150 HP, 480 V inverter duty motors are planned.
- Valves and Controls
- Ventilation and boiler system
- Three low voltage VFD's
- Power feeders
- MEP
- Piping connections
- 200 feet of 30" water main
- 600 feet of 36" water main
- Site work, paving, & utilities

Can Co → Start new 2015 HP L. Horn Rd to Dort Pump sta. tie to North River & use Cable wire

Phase 1	Phase 2
Filter Transfer Pump Station	

Item 7 – SCADA

As new pumps, chemical systems, and controls are installed; instrumentation and monitoring should be provided. It is proposed that the SCADA network is upgraded to current technology and software and training provided in the initial phase.

Phase 1	Phase 2
SCADA Network Upgrade	SCADA Hardware (Phase 2)
Software and Training	
SCADA Hardware (Phase 1)	

Can't be part of Gen. cont's backup

Item 8 – Raw Water Piping Connection

The proposed KWA raw water pipeline will connect to the existing 72" PCCP finished water supply line near Center and Pierson Roads. (East of this connection, the 72" PCCP will be utilized by GCDC-WWS for distribution of finished water in the GCDC-WWS service area.) Raw water from Lake Huron will be conveyed to the WTP site via the 72" PCCP pipeline. On the WTP site, the 72" pipeline will be tapped for a 42" pipe and for a 36" pipe to convey raw water for treatment. The following work is proposed:

- Piping connections
- 900 feet of 42" water main
- 100 feet of 36" water main
- Roadway and site restoration
- Storm sewer relocation
- Control valve rehabilitation and replacement

Phase 1	Phase 2
	Raw water piping connections

3. Other Items to Address to Finalize Scope of Work

In addition to the upgrades proposed above, the following issues/questions need to be addressed before finalizing the scope of proposed upgrades to the WTP:

a) Options for handling / disposal of lime sludge from softening operations (during period Flint River is water source)
b) Requirements for CT and enhanced treatment
c) Impacts of using river as continuous supply (quantity, quality monitoring & control, reservoir operating levels)
d) Chemical storage options

Prysby, Mike (DEQ)

From:	Prysby, Mike (DEQ)
Sent:	Wednesday, March 20, 2013 12:10 PM
To:	'Daugherty Johnson'
Cc:	bwright@cityofflint.com; Shekter Smith, Liane (DEQ); Bloemker, Jon (DEQ); Benzie, Richard (DEQ); Busch, Stephen (DEQ)
Subject:	KWA Raw Water Capacity - City of Flint

Daugherty,

This email confirms our discussion this morning concerning the possibility of modifying a resolution to purchase 18.0 million gallons per day (MGD) of raw water from the KWA to 15.0 MGD. The MDEQ does not concur with the potential reduction to 15.0 MGD of raw water based on the capacity requirements under the Michigan Safe Drinking Water Act. This volume of raw water will not be sufficient in meeting Flint's maximum day demands (MDD) and the MDEQ will not support a contract between Flint and the KWA that provides only 15.0 MGD of raw water. The MDEQ is also concerned that an 18.0 MGD contract will only be marginal in meeting Flint's MDD. Our concerns are based on the following demand data on record as provided by the city.

- Flint's 5-year average day demand: 13.9 MGD
- Flint's 5-year max day demand: 21.6 MGD

Next, R 325.11204 (1) of the Michigan Safe Drinking Water Act, 1976 PA 399, as Amended and the Administrative Rules require a public water supply to provide sufficient capacity in the waterworks system to meet the finished water supply requirements and, in Flint's case, needs to consist of rated capacity from an approved surface water supply. Flint's capacity needs are also based on treated water; thus the capacity of available raw water will need to be slightly higher (2 to 3 percent) to account for the water needed for production at the treatment plant.

While we understand that Flint's population and water use has declined over the past 10 years, there are other important considerations for providing sufficient source capacity and these include:

- Flint has the potential to fill many existing industrial vacancies over the next 20 years. Additional capacity will be needed to meet this need.
- Potential permit bans and/or connection bans if MDD cannot be met under contracted capacity
- Water use restrictions measures if MDD cannot be met

- Flint needs to plan for future capacity requirements. Most future capacity plans allow for some increase in capacity to allow for expansion of residential, commercial, or industrial customer base
- Flint's 2011 Water Reliability Study's 2030 projected MDD is 24.0 MGD. This MDD is consistent with Flint's most recent water system Sanitary Survey prepared by the MDEQ.

If you have any questions concerning this matter, please call me at your earliest convenience.

3. Monitor Polymer Feed
4. Monitor Co2
5. Monitor Fluoride Feed

Karegnondi Water Authority (KWA)

The counties of Genesee, Lapeer and Sanilac, along with the cities of Flint and Lapeer established the KWA with the objective of utilizing Lake Huron as their primary source of water supply. The KWA, with the GCDC taking the lead, has received a competitive bid of $24.6 million which will allow the KWA to proceed with construction of two water intake cribs one mile into Lake Huron and one 78-inch intake pipeline to provide a capacity of 85 million gallons per day (mgd). The MDEQ – Saginaw Bay District issued the construction permit for the intake pipeline and cribs in August of 2012.

Other major project components will include a pumping station at Lake Huron, approximately 50 miles of 60-inch raw water transmission piping, a 620 Mgal reservoir, and a 36 mgd water treatment plant that will serve Genesee County. Raw water from the KWA will also be available for treatment at the Flint water treatment plant and distribution to the City of Flint. The entire project is expected to be completed and the Genesee County water treatment plant be placed into operation by January 2016. KWA estimates the cost of $272,000,000 for construction of the raw water supply system. The City of Flint and GCDC will also have additional costs for their treatment plants.

7/10/13 WTP Test Run Start & Back Water

Flint WTP Meeting 8/27/13

MDEQ Reqs to WTP op.

2 Phases — Get WTP ready for op.
via Flint River water to EWA
only
2½ – 3 yrs

WTP mtg 8/27/13 @ noon

Phase I — what to do now — ready for Flint
— Short design life if not used for EWA)
Phase II — Lake Huron

Issues:

1 O₂ / NOx tank — no 30 day supply

Providing 1 O₂ tank for O₂ / NOx
readings & 30-day supply

* 30 day supply to stabilize
Lake is supplier's backup 20-30 days
only 2 yrs Rwtn EWA could OK

* Could not maintain Ozone conc. for study
Geo on O3 study, lot N CL₂ demand
Analyzed Algae, Bact EA - Sign
20 mg/L O₂ 2-4 Log conc E coli
get rid of Glycerol / V TTHM

No cog.
Goal/Crypt. → CMOS - Flat-bed
$Zr O_3$ - got crypto
cert for

long term PLAN - mod A CL (ARC ONLY)
& before Dec)

Short-term PLAN to

if SAF Cy cert & not
need DSET for UTL up. → Flat Rock

— Coog Fed there 2 ; if we need
a New coog — poss. changes in Coog.
& maybe some equip changes

Item 2
Outland SUBSTA. Oracle - need help! } See Unicode
& switchgear then UTL A } Proj

* Concern on delays w. CONSTRAINTS on getting
Project done in Cmj w. Process

two indep sources —
* NOEC thought → 2 sep feeds did not help
cost of 2500 sf. 2003 outage
dc vs. 1500 / GEN. 3 (we will look at
En more LAN
acts)

Full GT ok load is ~ 3.6 MVA

Another 2 transformers could not run WTP center

1.5 MG

2 Gen or 2 Gen for Avg. Day - Could run 2 sub stations

Item 3 - out (across w. Dirt)

Item 5

PM1 new 15 MGD H.S. or VFD / Ventilation

PM2 2nd 15 MGD H.S.

Item 6 - not doing

Expansion of 5.9 MG to add new 1/2 of each of added PLCs

Item 7 - SCADA

Item 8 - Raw water connection

- Piping for hard back on incoming line

Now could use

Sludge - Gravity Road out

- Oval settling basins in WTC 2 w. end of

- behind Hole process (trays, studies) settling basins or conveyor system

- pump in / pump out separate → Low item 5

F. Hor re-cycle mbr if recycle
1 no decant water

SIZE
may be more cost-effective to build temp
Pressas & test out
Bio Read - not option
- Primary need to form a better sol'n for
Organon

Pot UV units - Photo II unit upgrade 2003
report
II or Sonics ? - cld fit the trans steriwaths
Doot - P.P.g not installed
as was furnished

UV can go in II
if cryptosporidium - validated units → ± IRMS
Dorney, UK

P for cost → All approved EM/Trans & how this
make outs - will this get approved?

Recirc — Above
take Doot out
Cost of O2/NaOCl $?
Eff. from — energy losses VS potential yield
need Cl_2 out
Security - IN

Seal at valves

P.S. ingress cut - ok

Imm 6 - out

SCADA -

Other Lime Sludge

Mod Pt Cl_2 in WTP to repl. 1 det feeder

- Ito-8 - solenoid in plug connection

Move Odet (int. P.S. transducer) to Mod 2

(* - Get refresh adj for review) -

From: Dan Potter <potter@twp.grand-blanc.mi.us>
Sent: Thursday, June 20, 2013 10:31 AM
To: Prysby, Mike (DEQ)
Subject: Grand Blanc Reliability Study

Mike,

We didn't address your comment no. 8 in the Reliability study, but there are only two interconnects between the City and Township at the locations noted in the report.
There is no interconnect in Kings Pointe.

Thanks,
Dan

Subject: DWSD back up agreement

Follow Up Flag: Flag for follow up
Flag Status: Flagged

Hello Steve and Mike. As you are aware, the City has undergone extensive upgrades to our Water Treatment Plant and it's associated facilities. Our intentions and efforts have been to operate our facility as the primary drinking water source for the City of Flint. Through consultation with your office and our engineering firm we've developed a system of redundant electrical systems, treatment processes and adequate finished water storage to negate the need for a signed back up agreement with DWSD due to their termination of our contract. Upon inspection of these facilities would you convey your concurrence that there is no regulatory requirement for us to sign a back up agreement with DWSD.

Thank you
Daugherty Johnson

WATER QUALITY ADVISORY COMMITTEE

CITY OF FLINT

OFFICE OF THE EMERGENCY MANAGER

Gerald Ambrose
Emergency Manager

TO: Wayne Workman, Deputy Treasurer
Treasury Department
State of Michigan

FROM: Jerry Ambrose, Emergency Manager
City of Flint

DATE: March 3, 2015

As the Emergency Manager for the City of Flint, I am charged with restoring the City government to financial solvency, and working to assure that the City moves forward on a financially sustainable basis. The steps taken over the past three years have been difficult. Taxes and fees have been raised, services and workforce reduced, and ongoing costs, including legacy costs, have been constrained.

The current controversy surrounding the provision of water, and the path for resolution, has a potentially significant impact on the progress that is being made. I am satisfied that the water provided to Flint users today is within all MDEQ and EPA guidelines, as evidenced by the most recent water quality results conducted for MDEQ. We have a continuing commitment to maintain water safety and to improve water quality, and have dedicated resources to assure this commitment will be made.

The oft-repeated suggestion that the City should return to DWSD, even for a short period of time, would, in my judgment, have extremely negative financial consequences to the water system, and consequently to the rate payers. By the most conservative estimates, such a move would increase costs by at least $12 million annually, with that amount achieved only by eliminating virtually all budgeted improvements in the system. For a system with Unrestricted Assets of only $740,745, according to the June 30, 2014 audited financial statements, the only recourse within the City's control would be to increase revenues significantly. And in my judgment, that would come from raising rates for water by 30% or more . Further, changing the *source* of the city's water would not necessarily change any of the *aesthetics* of the water, including odor and discoloration, since those appear to be directly related to the aging pipes and other infrastructure that carry water from the treatment facility to our customers.

This direction of discussion also deviates from what, in my judgment, should be the focus: How can we not only operate and maintain a system to assure the delivery of safe and quality water dependably, but significantly reduce the cost of water and sewer to the users? At an average of $149 per month for water and sewer service for a residential user, the cost is extremely high in comparison to surrounding areas, as well as most areas across the state, and creates a significant financial burden for many users. In my judgment, we should all be concentrating on how to reduce rates by 50% or more. Unfortunately, there are no easy or evident answers, and continuation of the status will be an impediment to the sustainable recovery of the City of Flint. It is a conversation that I expect we will have with the recently created Water Quality Advisory Committee.

My reasoning for this conclusion is as follows:

One of the decisions made in the context of beginning to eliminate deficits and to restore financial stability to the City of Flint was to increase water and sewer rates significantly – the only choice available to financially stabilize a system that as of June 30, 2012, had a deficit of $8,758,091. Another was to leave DWDS for the KWA because it offered the opportunity to lower future rate increases. A third decision was to utilize the Flint River on an interim basis when DWSD unilaterally terminated the City's contract for water purchase. That decision was made because it also offered an immediate cost savings opportunity which translated into the ability to upgrade the Water Treatment Plant without having to seek financing. It was a reasonable decision because of our experience in using the river in a back-up capacity, including test runs on a quarterly basis for several decades.

Unfortunately, the switch to the river as a primary source was more challenging than anticipated, and the harsh winter of 2013-2014 resulted in much more damage to the aging water infrastructure than in previous years. The result was the issuance of required notices that water exceeded established guidelines for safety as it could affect certain vulnerable populations, and some users of the system experienced unpleasant odors and discoloration. Some users also appeared to have had some negative reactions to the new source of water. However, as soon as the test results were known, City staff took immediate actions to address the concerns. These actions are evidenced today by the fact that MDEQ has certified that our most recent testing shows water from all testing sites to be well within acceptable guidelines. Additionally, the City is continuing to taking the necessary actions to assure that the water supply remains safe and that water quality continues to improve.

As the City has moved to address the situation, the suggestion continues to be made that the City should re-engage with DWSD and purchase water at least until the KWA pipeline is supplying water. As evidenced by the most recent letter from DWSD, such a decision would immediately increase the City's cost by $846,700 per month, or $10,160,400 per year, just for the fixed cost portion of the price. The actual *purchase* of water would be an additional fee, and dependent upon

the quantity purchased. We estimate the actual water purchase cost to average more than $1 million per month, for a grand total of approximately $22 million per year. Finally, the DWSD offer is conditioned upon the City (or presumably the KWA) agreeing to negotiate a long term contract (30 years) for back-up.

The $22 million annual estimate of increased costs to purchase water from DWSD would be minimally offset by an approximate $3 million in reduced operating costs, and could be further offset by an additional $9 million, but only if all funding for capital improvements to the system are eliminated. To eliminate all funding dedicated to repairing, stabilizing, and improving the system would be totally irresponsible and would have long term negative consequences to the City and to future rate payers.

As you are aware we have recently brought in outside expert assistance to evaluate the steps we have taken to assure that the water is safe and to continue to improve water quality. We are expecting specific recommendations within the next few weeks, and are committed to implementing those recommendations in a timely manner. Many steps have already been taken. I am confident that implementing their recommendations will assure a continuing supply of safe water as well as improved quality, and at far less cost than re-engaging DWSD.

We have also created a 40-member Water Advisory Committee and a 13-member Technical Advisory Committee to assure two-way communication with the public and users of the system. Those committees will begin to meet this week, and we look forward to answering their questions and receiving their input.

It is unfortunate that problems and concerns with quality have arisen, and we are working every day to address the issues that caused them. Maintaining safe water and improving quality is a top priority as we work to make the City of Flint an attractive place to live, work, study, and play.

CITY OF FLINT

OFFICE OF THE EMERGENCY MANAGER

Gerald Ambrose
Emergency Manager

TO: Wayne Workman, Deputy Treasurer
Treasury Department
State of Michigan

FROM: Jerry Ambrose, Emergency Manager
City of Flint

DATE: March 3, 2015

As the Emergency Manager for the City of Flint, I am charged with restoring the City government to financial solvency, and working to assure that the City moves forward on a financially sustainable basis. The steps taken over the past three years have been difficult. Taxes and fees have been raised, services and workforce reduced, and ongoing costs, including legacy costs, have been constrained.

The current controversy surrounding the provision of water, and the path for resolution, has a potentially significant impact on the progress that is being made. I am satisfied that the water provided to Flint users today is within all MDEQ and EPA guidelines, as evidenced by the most recent water quality results conducted for MDEQ. We have a continuing commitment to maintain water safety and to improve water quality, and have dedicated resources to assure this commitment will be made.

The oft-repeated suggestion that the City should return to DWSD, even for a short period of time, would, in my judgment, have extremely negative financial consequences to the water system, and consequently to the rate payers. By the most conservative estimates, such a move would increase costs by at least $12 million annually, with that amount achieved only by eliminating virtually all budgeted improvements in the system. For a system with Unrestricted Assets of only $740,745, according to the June 30, 2014 audited financial statements, the only recourse within the City's control would be to increase revenues significantly. And in my judgment, that would come from raising rates for water by 30% or more . Further, changing the *source* of the city's water would not necessarily change any of the *aesthetics* of the water, including odor and discoloration, since those appear to be directly related to the aging pipes and other infrastructure that carry water from the treatment facility to our customers.

This direction of discussion also deviates from what, in my judgment, should be the focus: How can we not only operate and maintain a system to assure the delivery of safe and quality water dependably, but significantly reduce the cost of water and sewer to the users? At an average of $149 per month for water and sewer service for a residential user, the cost is extremely high in comparison to surrounding areas, as well as most areas across the state, and creates a significant financial burden for many users. In my judgment, we should all be concentrating on how to reduce rates by 50% or more. Unfortunately, there are no easy or evident answers, and continuation of the status will be an impediment to the sustainable recovery of the City of Flint. It is a conversation that I expect we will have with the recently created Water Quality Advisory Committee.

My reasoning for this conclusion is as follows:

One of the decisions made in the context of beginning to eliminate deficits and to restore financial stability to the City of Flint was to increase water and sewer rates significantly – the only choice available to financially stabilize a system that as of June 30, 2012, had a deficit of $8,758,091. Another was to leave DWDS for the KWA because it offered the opportunity to lower future rate increases. A third decision was to utilize the Flint River on an interim basis when DWSD unilaterally terminated the City's contract for water purchase. That decision was made because it also offered an immediate cost savings opportunity which translated into the ability to upgrade the Water Treatment Plant without having to seek financing. It was a reasonable decision because of our experience in using the river in a back-up capacity, including test runs on a quarterly basis for several decades.

Unfortunately, the switch to the river as a primary source was more challenging than anticipated, and the harsh winter of 2013-2014 resulted in much more damage to the aging water infrastructure than in previous years. The result was the issuance of required notices that water exceeded established guidelines for safety as it could affect certain vulnerable populations, and some users of the system experienced unpleasant odors and discoloration. Some users also appeared to have had some negative reactions to the new source of water. However, as soon as the test results were known, City staff took immediate actions to address the concerns. These actions are evidenced today by the fact that MDEQ has certified that our most recent testing shows water from all testing sites to be well within acceptable guidelines. Additionally, the City is continuing to taking the necessary actions to assure that the water supply remains safe and that water quality continues to improve.

As the City has moved to address the situation, the suggestion continues to be made that the City should re-engage with DWSD and purchase water at least until the KWA pipeline is supplying water. As evidenced by the most recent letter from DWSD, such a decision would immediately increase the City's cost by $846,700 per month, or $10,160,400 per year, just for the fixed cost portion of the price. The actual *purchase* of water would be an additional fee, and dependent upon

the quantity purchased. We estimate the actual water purchase cost to average more than $1 million per month, for a grand total of approximately $22 million per year. Finally, the DWSD offer is conditioned upon the City (or presumably the KWA) agreeing to negotiate a long term contract (30 years) for back-up.

The $22 million annual estimate of increased costs to purchase water from DWSD would be minimally offset by an approximate $3 million in reduced operating costs, and could be further offset by an additional $9 million, but only if all funding for capital improvements to the system are eliminated. To eliminate all funding dedicated to repairing, stabilizing, and improving the system would be totally irresponsible and would have long term negative consequences to the City and to future rate payers.

As you are aware we have recently brought in outside expert assistance to evaluate the steps we have taken to assure that the water is safe and to continue to improve water quality. We are expecting specific recommendations within the next few weeks, and are committed to implementing those recommendations in a timely manner. Many steps have already been taken. I am confident that implementing their recommendations will assure a continuing supply of safe water as well as improved quality, and at far less cost than re-engaging DWSD.

We have also created a 40-member Water Advisory Committee and a 13-member Technical Advisory Committee to assure two-way communication with the public and users of the system. Those committees will begin to meet this week, and we look forward to answering their questions and receiving their input.

It is unfortunate that problems and concerns with quality have arisen, and we are working every day to address the issues that caused them. Maintaining safe water and improving quality is a top priority as we work to make the City of Flint an attractive place to live, work, study, and play.

RE: **Water Questions**

DATE: February 16, 2015

Over recent weeks the City of Flint has taken a number of measures to increase both the quality of water and the availability of information. Monthly Operating Reports are posted online approximately 15 days following the end of each month, a summary report is also posted with additional information of utility functions, and the City has increased the level of testing being performed on the water.

A nationally recognized vendor (Veolia North America) has been contracted to provide a detailed overview of City procedures and to make recommendations where they see areas of improvements.

The following questions and answers are provided for all interested parties, and are intended to provide transparent, detailed, and updated information that is pertinent to the City of Flint's water system.

City of Flint – Questions and Answers

Is it currently safe to drink City of Flint water?

Yes. Water from the City of Flint meets all of the EPA regulatory standards of the Safe Drinking water Act.

What can you say about the quality?
The City of Flint is committed to providing high quality drinking water to residents and businesses in the community, and has taken every precaution to ensure the water quality meets guidelines for safe drinking water. To ensure that tap water is safe to drink, the Environmental Protection Agency (EPA) prescribes regulations, which limit the amount of certain contaminants in water provided by public water systems. In addition the Food and Drug Administration regulations establish limits for contaminants in bottled water, which must provide the same protection for public health. The City of Flint tap water meets the guidelines set by both entities.

What is considered to be a contaminant?
Contaminants that may be present in water include microbial contaminants such as viruses and bacteria, and inorganic contaminants such as salts and metals, which can occur naturally. Pesticides, herbicides, organic chemical contaminants and radioactive contaminants could also be present.

It's important to note that **drinking water, including bottled water** may reasonably be expected to contain at least small amounts of some contaminants. But the presence of contaminants does not necessarily indicate that the water poses a health risk.

Will these contaminants make people sick?
The EPA requires that every water report must contain language addressing the fact that some people have comprised immune systems or conditions that make them more vulnerable to contaminants in drinking water than the general population.
A few examples are, an individual with a compromised immune system such as someone undergoing chemotherapy or an organ transplant, a person with HIV/AIDs or other immune system disorders. Some elderly people and infants can be particularly at risk from infections. These individuals and parents of infants should seek advice from their health providers. It's important to understand that this is the case with all public drinking water. It's not unique to water from the Flint River.

How often does the City monitor water quality?
The City monitors its water on a daily basis to assure that water quality remains within established guidelines. With the variances in water temperature, and the leakage and infiltration problems arising due to failure of parts of the distribution system, water quality did exceed, for a time, some of the established guidelines. This resulted in the issuance of the recent notices to the public. Once it was learned that some guidelines were not being met, the City's immediate focus was to bring water quality back within guidelines. The efforts taken to address non-compliance included increasing water flow through valve replacements and hydrant flushing and optimizing treatment processes.

What were the causes of increased levels of bacteria (including fecal) levels that I read about? Have the causes been sufficiently addressed? If not what needs to be done to prevent this from happening again?
As is the case with most systems which treat surface water, many factors contributed to the

environment which allowed bacteria to proliferate. One of the main factors in our case is that when water travels through the 600 miles of the City's distribution mains it will, at times, in certain areas of the city, reside in the system for different periods of time. Water purchased from the Detroit Water & Sewage Department is drawn from Lake Huron, chlorinated, and then it travels over 60 miles to reach the City. By the time the water reaches Flint it is stable and capable of withstanding this type of residency time with the system. Water drawn from the Flint River, specifically in summer months when the temperature is fluctuating, is more susceptible to being impacted by variables such as high residency times and increased chemical reaction. Over the recent three months the residency time of water in the system has been reduced to approximately one week.

The Department of Environmental Quality (DEQ) requires that a minimum of 100 tests be performed monthly for chlorine residuals at various locations throughout the system. When residual levels are too low, it creates an environment in which bacteria such as fecal coliform can grow. After switching sources, we encountered testing sites in June 2014 that were consistently returning low residual levels. Several of these sites became areas that total coliform was eventually detected and ultimately "boil water" notices were issued. A significant cause of this is attributed to aged infrastructure which includes broken valves.

The necessary repairs and adjustments have been made to bring bacteria to acceptable levels with the exception of one test site -- the 2500 block of Flushing Road, where low residual levels continue. The City expects and is actively searching for valve issues. The engineering firm LAN & Potter Consulting is working to develop a hydraulic model of the distribution system and have the ability to use unidirectional flushing that will assist in addressing areas where residual levels are low.

The City has done internal testing recently that shows all eight sites currently well underneath the Maximum Contaminant Level and the next official testing date is due to the DEQ by March 1st, 2015.

It was recently announced in the news that Governor Snyder gave Flint $2 million to fix the water problems? Is this true?
Yes. Under the state's Financially Distressed Cities, Villages and Townships Grant Program, Flint was awarded $2 million to help address some of the problems associated with an aging water distribution system. While the City of Flint is very appreciative of the grant, it's going to take a substantially greater amount to fully address the improvements needed.
The grant will cover two significant projects, one, to decommission the incinerator that will result in ~$400,000 in savings annually to the sewer fund and two, a complete leak detection performed on all of the large transmission mains in the City that will reduce water loss, thereby creating a savings in the water fund.

This issue did not happen before the switch from Detroit water to Flint water. Why now?
Switching to the Flint River has highlighted underground inconsistencies in the distribution system that have existed for decades. Over the last few years, the City has engaged in the development of a more effective and consistent preventative maintenance program and a Capital Improvement Plan that will result in a more reliable water distribution center over time.

Was it known prior to the switch from Detroit water to Flint water that there would be problems managing certain bacteria levels?
It was understood that the Flint River would be subject to variations due to temperature changes, rain events and would have higher organic carbon levels than Lake Huron water and would be more difficulty to treat. These facts were presented to and weighed by licensed staff, LAN engineering consultants and the DEQ. It was determined that Flint has the equipment and the capacity to meet the demands of treating river water.

So in the majority of cases, it's safe to drink Flint tap water?
Yes, as safe it possibly can be. However if a person has a compromised immune system then he/she should consult with her/his physician first. It is also safe to bath and brush your teeth using the water.

What about the "hardness" of the water?
The Flint River is a harder water source than water drawn from Lake Huron. Hardness is classified as having a higher mineral content than "soft water", with the main concentration being calcium and magnesium. Water hardness is not considered by the EPA to be a health hazard.
Water hardness has been known to impact things such as cleaning tasks such as laundry, dishwashing, bathing personal grooming, and has also been associated with some forms of skin irritation such as eczema.

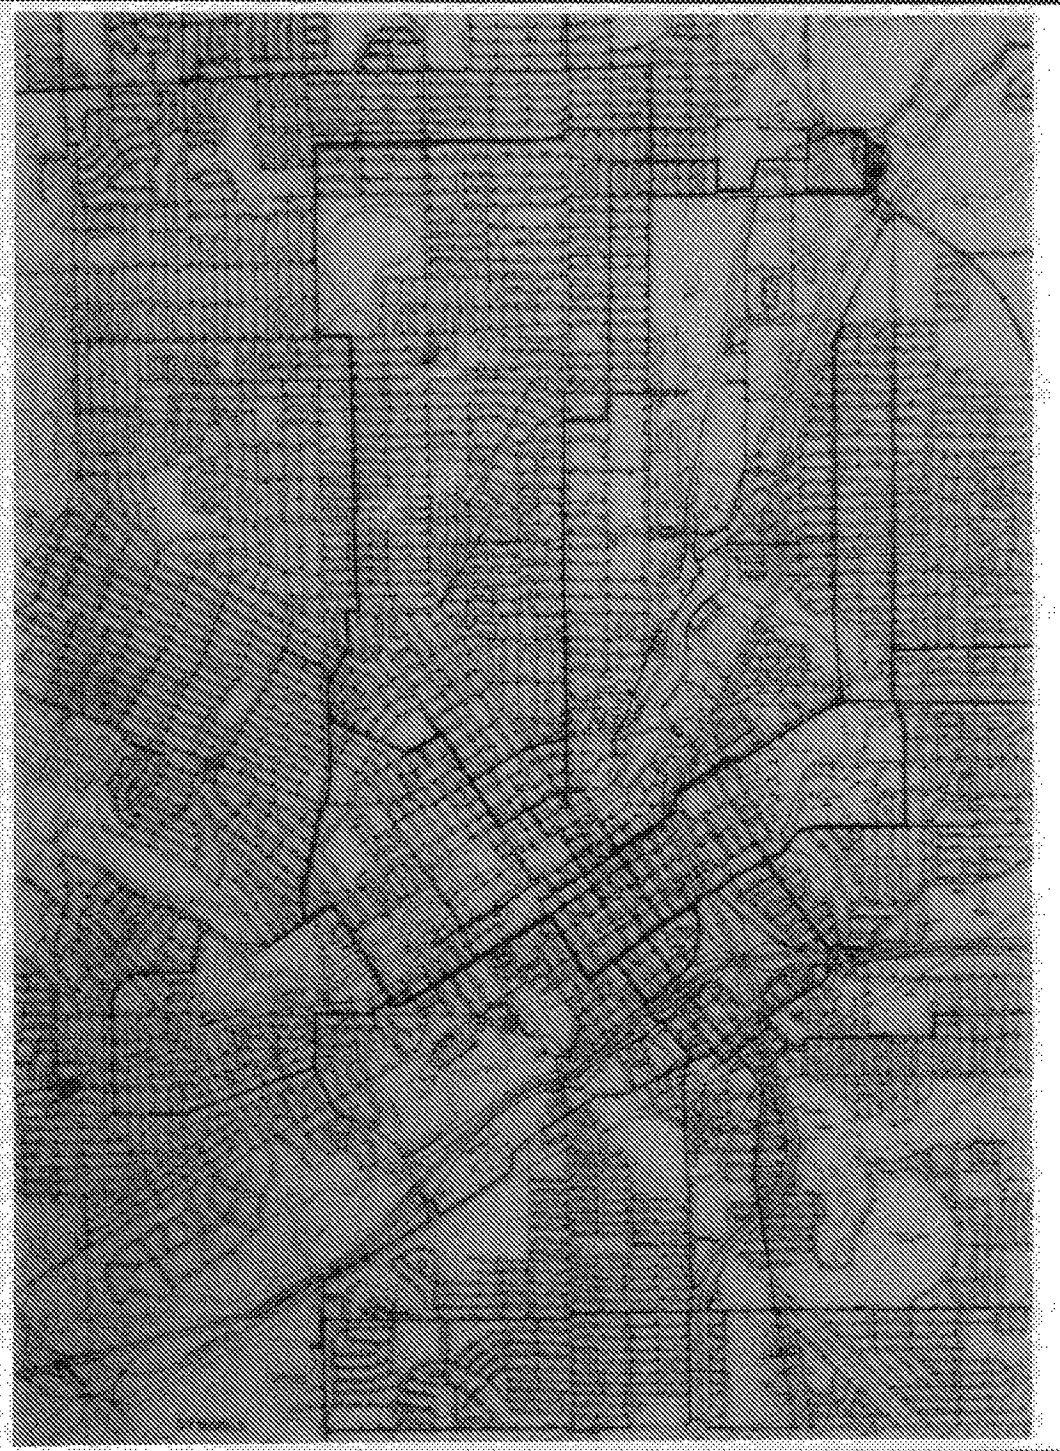
What are the public reporting requirements for these sorts of problems, and has the City met those requirements? What can be done to communicate useful information about a public health threat in timelier manner?

The EPA 2010 "Revised Public Notification Handbook" has a specific breakdown of the elements required in public notifications and includes usable templates. The EPA has three different tiers associated with community water systems (CWS), each with specific timeframes and requirements that trigger upon issuance of the violation.

- **Tier 1.** CWS must provide **public notification within 24 hours of a violation** and continue this as directed by the primary agency.
- **Tier 2.** CWS must provide **public notification within 30 days of a violation** and continue this every three months until the violation is resolved
- **Tier 3.** CWS must provide **public notification within one year** and the EPA recommends repeat occurrences be provided in an annual notice

The current violation is classified as a tier 2 violation and was issued December 16, 2014.

Besides the home notifications, where can I find official communications and any updates on the Flint water issue?
The City posts information on the City of Flint website at www.cityofflint.com. There is a special section dedicated to addressing Flint water concerns and providing up-to-the-minute updates. In



addition, updates can be found on Flint's Facebook page and citizens may also call the Flint Water Plant & Facilities at 810-787-6537 with questions.

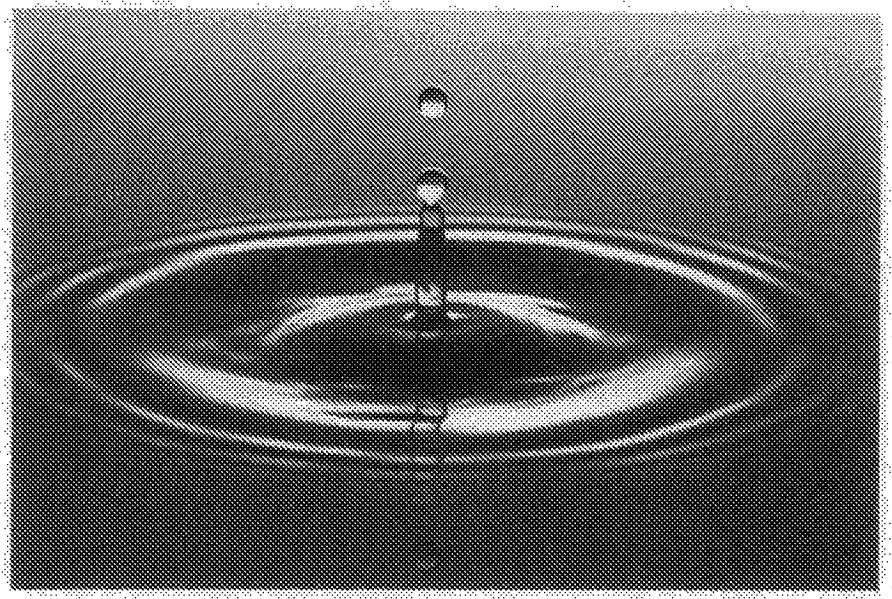
If the water is ok to drink, why did GM stop using the water?

General Motors has been A great partner to the city for many years and when they recognized that an elevated level of chloride in the water was having an impact on a specific machining process they requested permission to transfer water delivery for that specific process to Flint Township. This represents only 10% of the water purchased and used by GM at the entire site. The remaining 90% of their water usage including all of the drinking water for GM employees is still purchased from the City of Flint.

Respectfully Submitted,

Howard D. Croft
Public Works Director

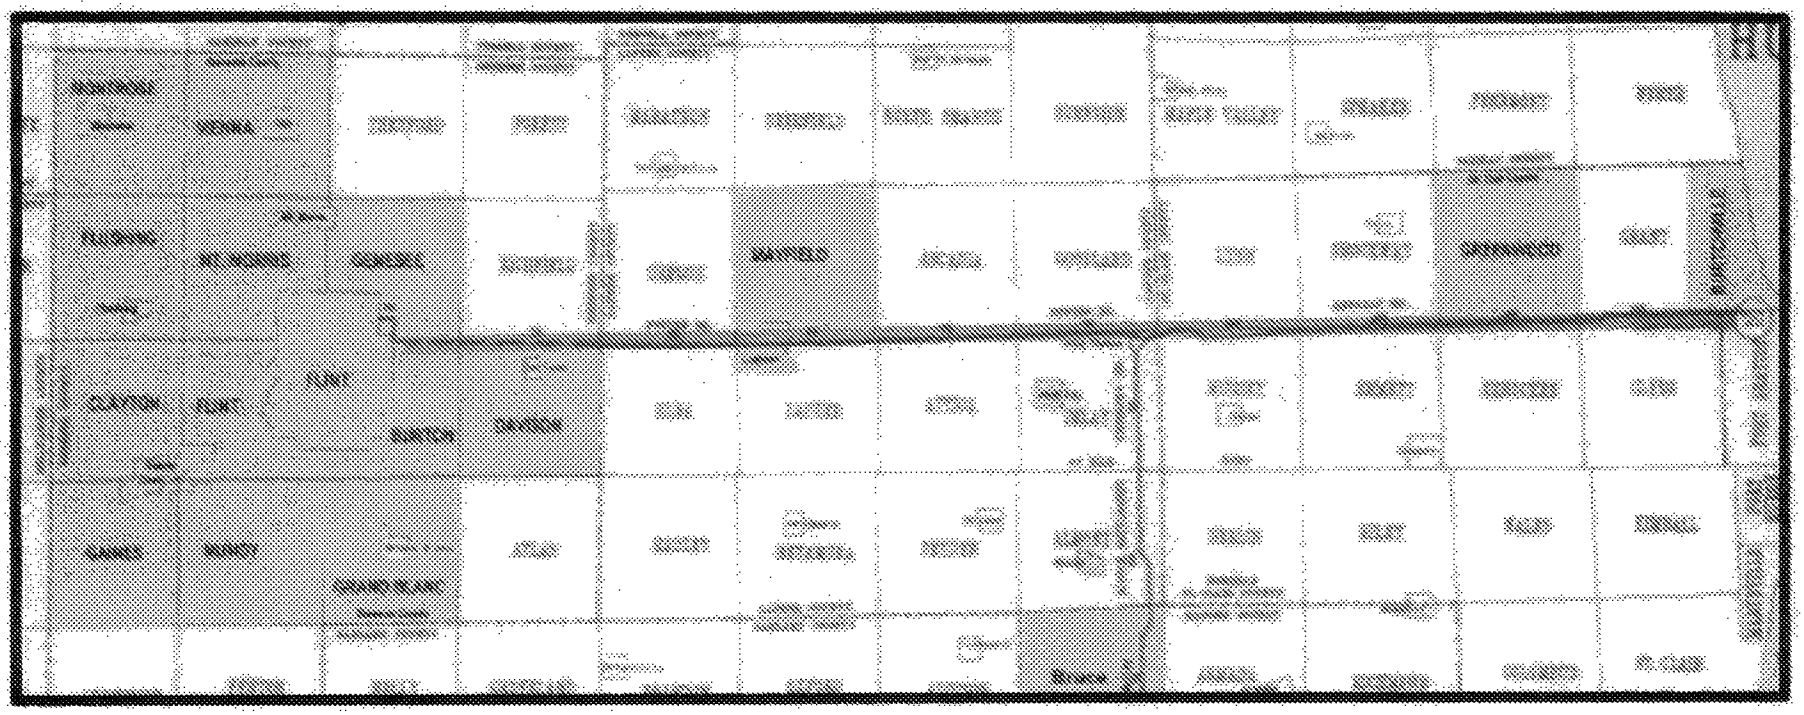
City of Flint
Water System Facts



Over 600 Miles of Distribution Mains

Over 7000 Valves
Over 3909 Hydrants

Over 46,000 users in 2006
Only 31,000 users in 2014

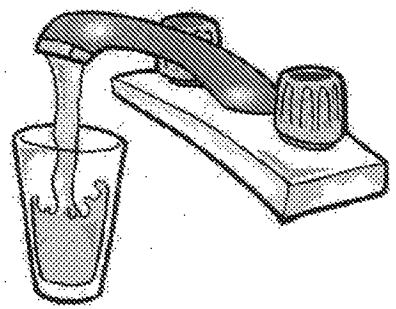


What Can Impact Water Quality ?

- Condition of source water
- Temperature
- Organic material
- Retention time in system
- Low flow
- Dead ends
- Main Breaks
- Repairs

Quality Indicators

- Chlorine residual
- Total coliforms



Flint River

DWSD

CITY TESTING

- 10 test sites around the city
- Tests are performed manually 2 – 3 times a week
- Over 100 Tests are performed a month
- All tests are reported to the DEQ for oversight
- Tests are performed EVERY four hours inside the Plant
- The City responds to and tests all reported concerns

City of Flint
Water Improvements since November 2014

DATE	IMPROVEMENT	EFFECT
Nov.	Increased flushing efforts (as weather permits)	Reduced time of water in the system
Nov.	Adjusted operational softening to no less than 80%	Reduce chlorine demand
Dec.	Started hydraulic modeling of distribution system	Helps to identify locations of bad valves
Dec.	Started evaluation of different polymers	Removal of organic carbon
Dec.	Started SCADA upgrades inside of Water Plant	Improvement of internal software controls
Jan.	Hired vendor to upgrade efficiency of the ozone system	Better oxidation and disinfecting
Jan.	Started jar testing	Assists in dosage amounts and polymer aids
Feb.	Hired consultant Veolia for process review	Professional recommendations
Feb.	Leased and installed TTHM analyzer	Increased internal testing ability
Feb.	Adjustments to reservoir level to match demand	Reduce time of water in system

City of Flint
Water Timeline

Legend

△ TTHM Quarterly Testing

● Specific Dates of Events

October 3rd - City receives engineered estimates on the ability to upgrade the Flint Water Plant along with costs estimates.

Summer- City of Flint experiences multiple boil water advisory notices, complaints about smell, taste, and discoloration of water.

January 2nd - City releases violation letter to the public via U.S. mail.

February 27th - City receives results from the state lab showing that Feb. quarterly results are all well below the MCL

March 4th & 5th - City of Flint holds first two advisory committee meetings..

Nov Test
(1 of 8) > MCL

2013 2014 2015 2016 2017

May Test
(6 of 8) > MCL

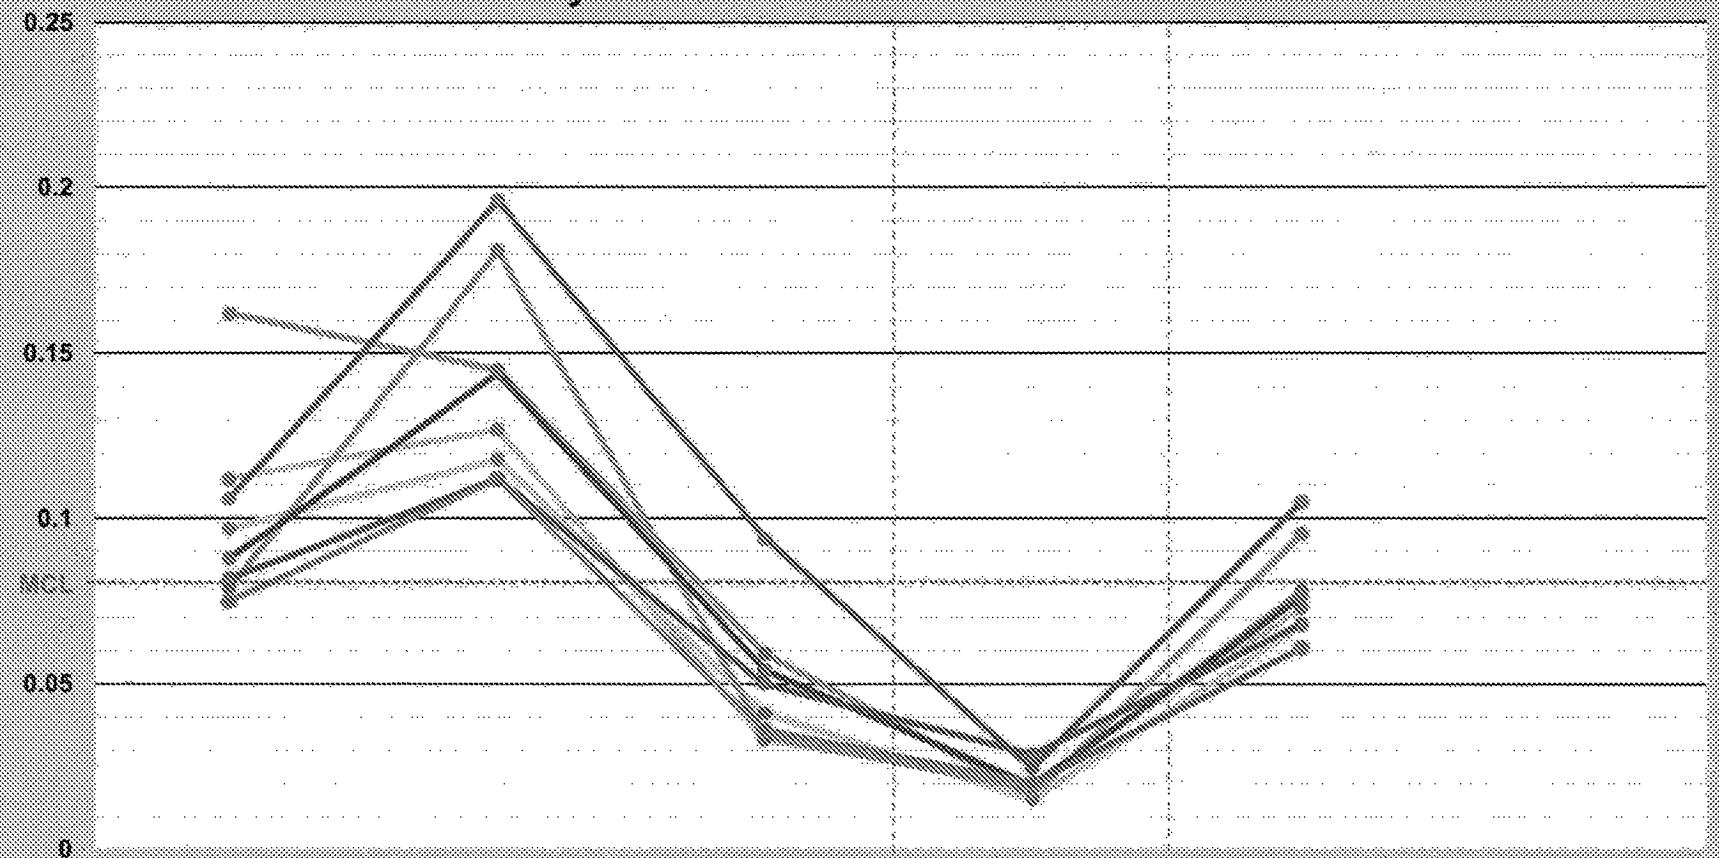
Aug Test
(8 of 8) > MCL

Feb Test
(0 of 8) > MCL

April 18th - City of Flint signs agreement with KWA.

DWSD terminates existing contract ~24 hours later.

April 30th - City of Flint officially closes all valves to complete the separation from DWSD water source.



November 7th - City of Flint staff and engineering team meet with DEQ to discuss Quarterly TTHM results and begin drafting OER

December 18th - City receives official violation notice from DEQ

February - City of Flint signs contract with Veolia for additional review and recommendations.

Summer - **KWA raw water expected to reach Flint Treatment Plant.**

Flint Water
Technical Advisory Committee
May 20, 2015
Flint City Hall

Agenda

2:00 pm	**Welcome** **Purpose of the Technical Advisory Committee: Provide a respectful means of sharing factual information and having dialogue around the City of Flint water.**
2:05 pm	**Introductions**
2:10pm	**Current water status information – M. Glasgow, Operator In Charge (F-1)**
2:20 pm	**Improvements information – H. Croft, Director Department of Public Works** New filter media installation Leak detection New pipe installation Water meter installation New water page on City website ⟶ Live by next June - More web page for residents
2:40 pm	**Discussion on next TTHM testing expectations** ⟶ ⟶ TTHM → the water
2:50pm	**Discussion on current health concerns, including lead and copper testing**
3:30pm	**Next Steps** Next meeting, one month or two months?
3:35 pm	**Adjourn**

City Of Flint Water History Facts

Current Treatment Plant was put into service in 1954.

Current 72" main pipeline was completed in 1970.

Flint signed a 30 year contract with Detroit water and Sewer Department in the mid 1960's.

The contract with DWSD has expired and we are currently operating on a yearly extension.

In 2006 Flint completed a $48,000,000 upgrade of the existing Water Plant. (Required by the MDEQ & for backup only).

Flint's Water & Sewer System is approximately a 300,000,000 Enterprise.

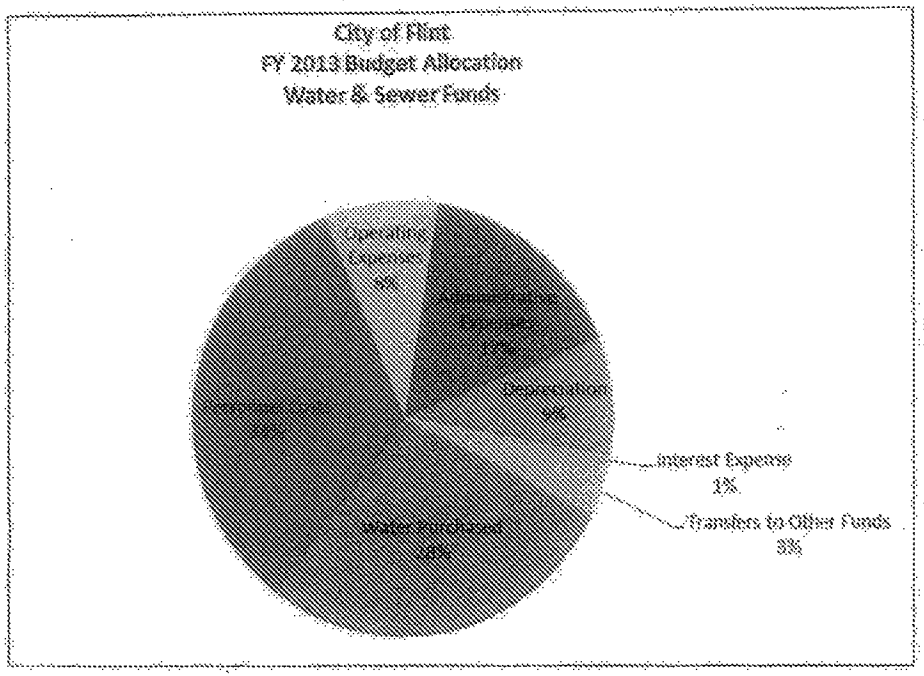
Flint's Water & Sewer System is designed to deliver water to over 200,000 people with over 1,500 miles of infrastructure.

Flint's most recent census count shows a population of approximately 102,000 in 2010.

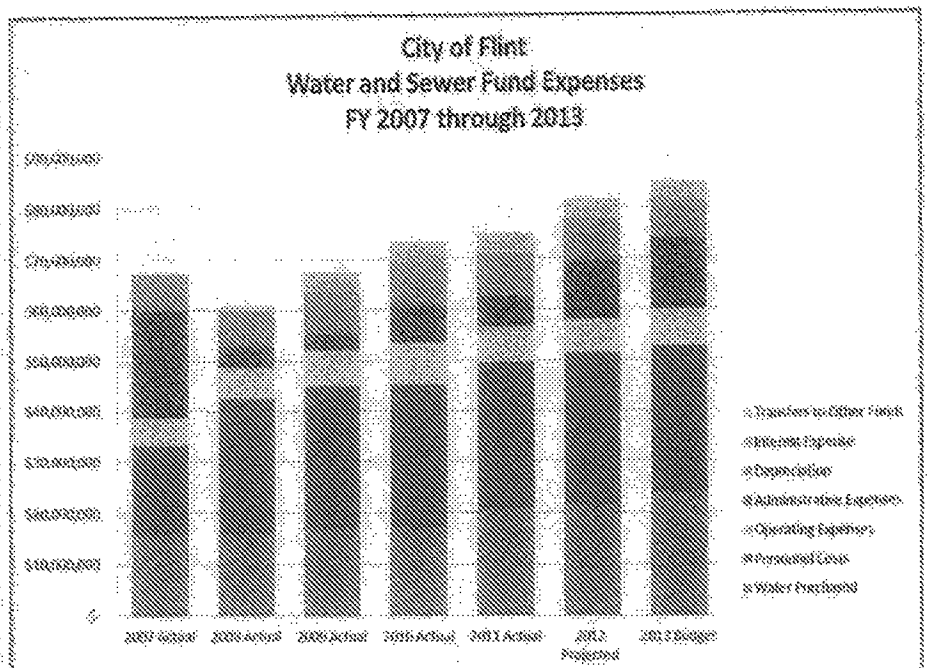
Flint's census population in 2000 was approximately 124,000.

The water system had over 45,000 customers in June of 1999.

The water system had just over 36,000 customers by June 2011.



The "Fixed Costs" that must be covered to maintain the system and deliver quality water have increased over time.



City Of Flint
Most Frequently Asked Questions about Water

- ❑Why are the water rates so high ?
- ❑How does my water bill work (Explanation of charges) ?
- ❑Why do others in the area pay less for the same amount of water ?
- ❑Where has all of the water and sewer fund money gone ?
- ❑What do I do if I think my bill is incorrect ?
- ❑What effect does leakage or theft have on my bill ?
- ❑How can I report water theft ?
- ❑Why don't we go back to using the Flint River like we once did ?

CITY OF FLINT
WATER NON-PAYMENT TURN-OFF POLICY

1. Water services to any customer may be shut off if the account is not paid until after 30 days after the due date. (City ordinance 46-52 (h))

2. Non-payment turn-offs are done only Monday through Thursday. The Customer Service Center does not schedule non-payment turn-offs on Fridays, Saturdays, Sundays, or most recognized holidays.

3. Illegal usage, broken payment arrangements and NSF (non-sufficient funds) turn-offs are done at any time without additional notice.

4. Turn-off notices are mailed to delinquent customers fifteen (15) days before actual turn-off.

5. The water customer is responsible for maintenance of all plumbing in the premises including connection to City water mains or sewer lines.

6. If a customer disputes a water bill and is unable to resolve the issue with Customer Service personnel, the customer may request an administrative review. Further information on any water account may be obtained by calling (810) 766-7015 or visiting the Customer Service Center at 1st Floor, City Hall, 1101 S. Saginaw St.

Preliminary Options for Future City of Flint Water Sources

Consider a New Negotiated Contract with Detroit Water and Sewer Department

PROS	CONS
No upfront capital costs	Lack of control over new / fixed changes
Possibility to negotiate a lower rate	Past practices
Ability to "Blend" water sources to further control costs	

Consider a Contract with the Karegnondi Water Authority

PROS	CONS
Voting member of KWA board	Capital cost (debt service)
Ability to "Blend" water sources to further control costs	Uncertainty of final costs
Raw water is an asset for attracting new buisnesses	

Blended Use of the Flint River

PROS	CONS
Helps contro cost of water	

*** CURRENTLY NO DECISIONS HAVE BEEN MADE REGARDING THE FUTURE WATER SOURCE

Improvements for City of Flint Water System

Reduce Leakage

- **Finalize a Preventative Maintenance Plan**
  - (Planning started in January 2012, requires funding, … part of Operational Costs)
  - Will help identify repair area's

- **Reduce water theft**

- **Replace water meters**
  - We currently have an eighteen month plan to replace all meters with more efficient "*Smart Meters*"

- **Encourage routine household checks**
  - "Faulty" toilets are a significant reason for household water loss. and unexpected larger bills.

Other Leakage concerns

✓Transmission Loss

✓Fire Hydrants

✓Incorrect water bills

✓Non-Payment

City of Flint
Water Improvements since November 2014

DATE	IMPROVEMENT	EFFECT
Nov.	Increased flushing efforts (as weather permits)	Reduced time of water in the system
Nov.	Adjusted operational softening to no less than 80%	Reduce chlorine demand
Dec.	Started hydraulic modeling of distribution system	Helps to identify locations of bad valves
Dec.	Started evaluation of different polymers	Removal of organic carbon
Dec.	Started SCADA upgrades inside of Water Plant	Improvement of internal software controls
Jan.	Hired vendor to upgrade efficiency of the ozone system	Better oxidation and disinfecting
Jan.	Started jar testing	Assists in dosage amounts and polymer aids
Feb.	Hired consultant Veolia for process review	Professional recommendations
Feb.	Leased and installed TTHM analyzer	Increased internal testing ability
Feb.	Adjustments to reservoir level to match demand	Reduce time of water in system

Flint Water Advisory Committee First Meeting
March 5, 2015 2-4pm MTA Auditorium

Agenda

Committee Members will receive a packet at the entry with their name tag, question sticky notes, pencil and other sources of information.

I. **Welcome and Introduction of Facilitators**

II. **Facilitator Ground Rules and Agenda Review**

Purpose of the Water Advisory Committee: Provide a respectful means of sharing factual information between the City of Flint and the Flint Water and Sewer Customers

The meeting will follow the printed agenda.

The meeting must conclude at 4pm today. The Facilitator will keep us on track.

III. **Expected Outcomes:**

Today's meeting: that all of the water questions have been identified – we may not be able to answer all today, but we would like to set up a means of communicating with this committee on a regular basis.

Through 2016 – That the transition to KWA water processing and distribution is a smooth, satisfactory process resulting a safe, consistent water supply.

IV. **Status of Water and Distribution System Today – H. Croft, Director Department of Public Works**

Evaluation of Flint Water Treatment Plant and Distribution System – Veolia, City of Flint Consultant

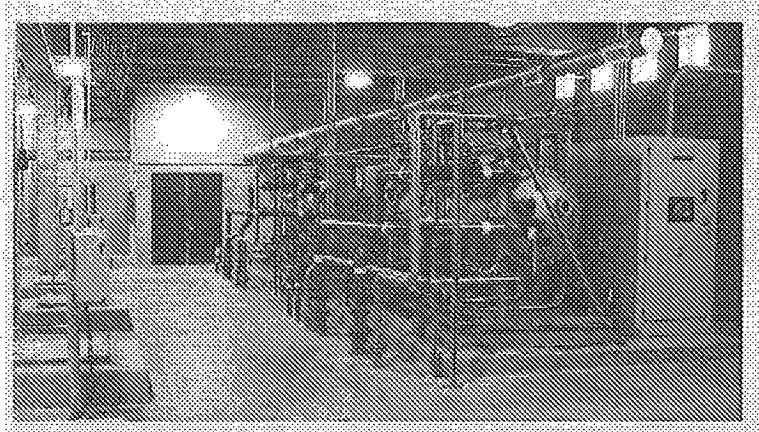
V. **Questions from Committee Members and Sort by Category: Safety, Quality, Affordability, Sustainability, History, and Miscellaneous**

VI. **Response to most frequently asked questions.**

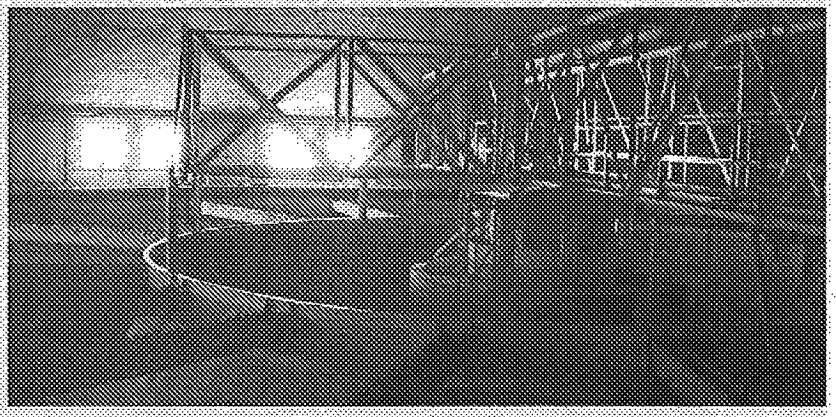
VII. **Next Steps**

The next meeting has been scheduled for Thursday, March 19, 2015 here at the MTA Auditorium from 2-4pm.

How often would the committee like to meet? How did this format work?



VIII. **Adjourn**



Operational Evaluation Report

EXECUTIVE SUMMARY

Environmental Protection Agency (EPA) and Michigan Department of Environmental Quality (MDEQ) regulations require that public water suppliers test drinking water quarterly throughout the distribution system for disinfectant by-products (DBP's). Two categories of DBP's, tri-halomethanes (THM) and halo-acetic acids (HAA5), are regulated and must be tested for. The City of Flint began operation of their water treatment plant (WTP) full time with the Flint River as the source on April 25, 2014. Since that time, two quarters of samples taken indicate that future violations are inevitable for total THM without some modifications to the water system. In response, the City hired Lockwood, Andrews & Newnam, Inc. (LAN) to complete this Operational Evaluation Report (OER) in conformance with EPA guidelines with the goal to determine the cause(s) of high levels of THM and evaluate possible solutions.

The EPA promulgated the Stage 2 Disinfectants and Disinfection By-Products Rule (DBPR) in January 2006 which set maximum contaminant levels (MCLs) for total trihalomethanes (TTHM) and HAA5 based on an annual running average, tested quarterly, for a given sampling location. The City of Flint reports levels from 8 sampling test locations. Of the two quarterly sampling cycles since Flint began operating the WTP full time, HAA5 levels have been acceptable but TTHM levels have been high at all 8 sampling sites.

According to the Stage 2 DBPR, the annual average value requires 3 quarters of sampling data with the most current period counting twice. Therefore, the City of Flint has not yet experienced a violation of the TTHM MCL because only 2 quarters of data have been obtained. However, levels recorded indicate the likelihood of an MCL exceedance later this year.

A number of issues have been identified as possibly contributing to the high THM levels measured.

1. Inefficient ozone system functionality which has resulted in increased chlorine feed.
2. Upstream influences in terms of increased chlorine demand.
3. Bypass stream around softening contributed to chlorine demand.
4. Unlined cast iron pipes in the distribution system contributing to chlorine demand.
5. Recirculating water in the distribution system due to less than ideal configuration of Cedar Street and West Side pump stations.
6. Broken valves resulting in stagnant water in some areas.
7. High chlorine demand in filters.
8. High THM formation potential (THMFP) in source water.
9. Less than optimal removal of THM precursors

ACTION PLAN

The City of Flint has signed an agreement with the Karegnondi Water Authority (KWA) to purchase raw water drawn from Lake Huron. The KWA system is currently under construction and expected to be operational by late 2016. The water supply from Lake Huron will have entirely different water quality characteristics from the Flint River and those characteristics are expected to yield drastically reduced DPB formation. With that, non-structural options to help reduce THM levels are much preferred over solutions requiring new construction. Therefore, two categories of actions have been devised: Stage 1 being actions that can be completed relatively quickly without major construction and Stage 2 consisting of either long term actions or solutions requiring major construction. The City has completed or intends to complete Stage 1 Actions by February 16, 2015, the week in which the next quarterly sampling is to be done. Stage 2 actions are to be implemented only if Stage 1

4 night runs - Lost 2 over new tubing and

= Ozone - Ozone to come out (new year) to shut - uses system to shut

= Still using a Retrack mixing & vent II not at steroids

actions are ineffective in adequately reducing TTHM levels and therefore Stage 2 is contingent upon the outcome of Stage 1.

Stage 1 – Immediate Actions

- Hire ozone system manufacturer to troubleshoot ozone system
- Bench scale jar testing
  - Match existing process and access possible areas of improvement
  - Simulate potential modifications to treatment process
  - Evaluate coagulation and flocculation polymer aid feeds to assist with TOC removal
- WTP operational changes
  - Discontinue softening bypass stream to reduce chlorine demand
  - Disinfection of filter beds to reduce chlorine demand
  - Possibly begin coagulation and flocculation polymer aid feeds to assist with TOC removal depending on bench scale test results
- Increase water main flushing efforts to minimize stagnant water
- Water system modeling to identify areas with high water age and potential solutions
  - Cedar Street Pump Station potential recirculation
  - West Side Pump Station potential recirculation
  - Storage tank volume use
  - Possible broken closed valve locations
  - Locations in need of flushing
  - Lower high water levels in storage tanks

Stage 2 – Contingent Actions

- Fix ozone system
- Start feeding coagulation and flocculation polymer aids to lower TOC, if not completed in Stage 1
- Convert to lime and soda ash softening
- Change disinfectant to chloramine or chlorine dioxide until KWA
- Install pre-oxidant feed at intake to optimize ozone disinfection
- Implement advanced treatment for THM precursor removal
- Increased main flushing based on water modeling results
- Continue valve replacements with water model assistance
- Emphasize cast iron pipes on water main replacement priority list

Model 4 is running

potential for reprogramming

I. BACKGROUND

The City of Detroit Water and Sewer Department (DWSD) has historically provided drinking water for the City of Flint and Genesee County. In the late 1990's growing concern regarding the reliability of the DWSD supply prompted the City of Flint to upgrade their existing water treatment plant (WTP). Those improvements, defined as Phase I, were completed in 2005 and were intended to allow the Flint WTP to operate, using the Flint River as the source, for an extended period of time in the event that supply from the DWSD was temporarily interrupted. Additionally, the Phase I improvements set the stage for Flint to break free from dependence on the DWSD supply and water charges over which they had no control.

A. WATER SUPPLY TRANSITION

1. Detroit Water and Sewer Department (DWSD)

Until recently the Genesee County and Flint region had been provided drinking water by the DWSD. However, due to excessive cost increases and reliability issues with the DWSD system other options had to be explored.

2. Karegnondi Water Authority (KWA)

In 2010 the Karegnondi Water Authority (KWA) was formed for the purpose of developing a new water supply from Lake Huron to serve the region in lieu of the DWSD supply and the City of Flint elected to join. The KWA expects the new system which is currently being constructed to become operational in the fall of 2016.

3. Flint River – Interim Period

With a renewing water supply agreement between Flint and the DWSD being terminated by the DWSD (effective April 30, 2014) and the KWA system not expected to be operational until late 2016, the City of Flint decided to initiate operation of the existing WTP full time utilizing the Flint River as the interim water source. A variety of WTP improvements were necessary for the Flint plant to become a full time plant. For purposes of this report, Phase II improvements to the Flint WTP are improvements which have been made to allow the plant to operate full time with either the Flint River as the source or the KWA supply as the source.

B. TTHM PENDING VIOLATIONS

The calculation for determining if the MCL has been violated for TTHM is:

(2 x current quarter value + previous 2 quarter values) / 4

Flint has completed tests for 2 quarters and therefore has not violated an MCL limit to date. However, the third quarter of sample data is likely to provide MCL exceedances at all 8 sampling sites. Test results are tabulated below.

DRAFT

TABLE 1 – 2014 DBP TEST RESULTS						
Sample Location	TTHM			HAA5		
	1st Qrt 5/21/14	2nd Qrt 8/21/14	3rd Qrt	1st Qrt 5/21/14	2nd Qrt 8/21/14	3rd Qrt

8) 6204 N. Saginaw – N. Flint Auto	79.2	118.3		50	37	

TTHM MCL = 80 ug/l
HAA5 MCL = 60 ug/l

C. WATER TREATMENT PLANT RECENT IMPROVEMENTS & STATUS

1. Phase I WTP Improvements

Since 1965, the Flint WTP has remained a secondary or backup supply system to the DWSD primary supply. Typically the secondary supply for a public water system is expected to be needed only during emergency situations and normally is designed for short term operation such as providing the average daily demand for a few days. Conversely, Phase I improvements were designed with the intent to upgrade the Flint WTP in order to allow for an extended short term period (6 weeks) because of the perceived high risk that the DWSD supply would fail and remain out of service for an extended duration. Regardless, the Flint WTP was still intended to serve as a standby plant and as such the Phase I improvements lacked redundancies that would be required for a primary supply WTP.

2. Past Pilot Study & Testing

During design of the Phase I improvements a treatability study was completed by Alvord, Burdick & Howson, LLC (AB&H) in 2002. The Treatability Study evaluated the current treatment processes that are in place at the Flint WTP today with the Flint River as the source. The report recommended the following:

TABLE 2 – 2002 WTP TREATMENT RECOMMENDATIONS			
Treatment	Purpose	Point of Application	Dosage (mg/l)
Sodium permanganate	Zebra mussel control	Intake	0.3
Ozone	Taste & odor removal, disinfection	Diffusor basin	1.5
Ferric chloride	Coagulation	Rapid mix	40
Coag aid polymer	Turbidity & TOC removal	Rapid mix	2.0
Floc aid polymer	Turbidity & TOC removal	Floc basin	0.05
Lime	Softening	Softening basin	175
Soda ash	Softening	Softening basin	52
Carbon dioxide	pH adjustment	Recarb basin	37
Media filters	Filtration	Na	Na
Chlorine	Disinfection	Filter effluent	1.0

Of the recommended items, zebra mussel control, coagulant and flocculation polymer aids, and soda ash feed have not been incorporated into the treatment process.

3. Phase II WTP Improvements for Full Time Operation

Phase II WTP improvements are those needed to convert the Flint WTP from a back-up supply to a primary supply plant. A number of improvements have already been constructed as they were necessary to operate full time, treating water from the Flint River. The improvements under the title of Phase II that have been completed or are nearly complete include upgrades to the lime sludge lagoon, the lime sludge lagoon decant and disposal system, decant pump station and force main, installation of mid-point chlorination before filtration, and upgrade of the electric feed sub-station.

Additional improvements to the Flint WTP that are to be completed to become part of the normal treatment process using water supplied by the KWA are:

- New oxygen and nitrogen storage facilities for the ozone system (under construction)
- New coagulant feed system
- Electrical
  - Pump Station #4 upgrades (under construction)
  - SCADA and controls upgrades
  - Filter transfer pump station feeders
- Installation of the future raw water feed connection point for the KWA (under construction)
- Pump replacements and VFD installation in the low and high service pump station (under construction)
- Filter transfer pump station to Dort Reservoir
- Facility security improvements

DRAFT

II. SOURCE WATER EVALUATION

A. DATA ANALYSIS

Based on past data collected and the 2002 Treatability Study by AB&H, the Flint River water quality varies seasonally with higher hardness and alkalinity experienced in the winter. Higher magnesium concentrations are also experienced in the winter, adding difficulty to the settling process due to neutrally buoyant floc. General water quality average characteristics recorded for the 2002 Treatability Study as compared with average characteristics recorded this year are shown in Table 3 below.

TABLE 3 – FLINT RIVER WATER QUALITY CHARACTERISTICS

Period	Turbidity NTU	TOC Mg/l	Alkalinity Mg/l	Hardness Mg/l as CaCO3	pH	Total Col. Count/day
2001 Apr–Oct	7.9	9.4	215	272	8.1	870-1230 (7300 max)
2014 May–Oct	8.3	10.3 5/22/14	207	252	8.2	1900-9000 (48,300 max)

Other than total Coliform, the Flint River characteristics do not appear to have changed significantly over the past 10+ years. Note that further investigation by City staff revealed a sewer leak upstream of the plant that may have contributed to the total Coliform count. The leak was subsequently repaired.

B. CONCLUSIONS

Considering the minor changes in Flint River water quality, much of the information contained in the 2002 Treatability Study by AB&H remains relevant today. Data from that report assumed to be consistent today include the following:

- Flint River is influenced by groundwater from a dolomitic aquifer
- Hardness varies seasonally with higher hardness and alkalinity in the winter
- Hardness, alkalinity, magnesium concentrations tend to be reduced by run-off
- Total THMFP is likely 380-440 micrograms per liter as measured between April 2001 and January 2002. The City intends to re-test the raw water to confirm the THMFP has not changed. Results are pending.

In development of the 2002 Treatability Study, processes were simulated which resulted in low THMFP. Therefore, information contained in that report will be used to assist with establishing a baseline jar testing procedure as discussed further in Section III.

III. TREATMENT PROCESS EVALUATION

A. EXISTING PROCESS DESCRIPTION

The existing WTP consists of an intake with screening from the Flint River, low lift pumping, ozonation, rapid mix, flocculation, settling, softening, recarbonation, filtration, storage and high service pumping. A process diagram is shown as Figure 1.

1. Intake

A 72" diameter pipe draws water from the Flint River through 2 traveling screens to the low lift pump structure. No chemicals are currently fed for Zebra mussel control or pre-oxidation as recommended by the 2002 Treatability Study. Manual removal of zebra mussels proved to be more economical than installation of chemical feed equipment considering the short term need.

2. Ozone

There are 2 ozone generators designed to provide adequate ozone for a WTP flow of up to 36 mgd. There are 3 ozone contact basins. The ozone generators were designed to produce 900 lbs/day at 10% concentration and up to 1300 lbs/day at 6% concentration each. Recent readings have indicated a production rate of approximately 700 lbs/day at 4% concentration. While serving the purposes of taste and odor control and disinfection, it is possible the current ozone feed might not be optimized to realize additional TOC removal benefits demonstrated by previous tests. Also, less than optimal ozonation has led to increased chlorine feed.

3. Rapid Mix

East and West rapid mix chambers allow chemical feed prior to the flocculation basins. Each rapid mix chamber is equipped with a 5 hp mixer.

4. Coagulation / Flocculation

The WTP contains two equally sized flocculation basins, east and west, and each basin provides tapered or gradually slowed mixing from inlet to outlet. There are fifteen 2 hp mixers for each basin with VFDs to control mixing speed. The 2002 Treatability Study recommended feeding both coagulation and flocculation polymer aids. Neither polymer aid is being used today because turbidity and TOC removals have been sufficient to meet regulatory requirements.

5. Settling

Primary clarification takes place within 3 basins containing plate settlers. The settlers are operating as designed.

6. Softening

Again, there are two basins for softening: east and west. Each basin is 120' in diameter and contains a solids contact softening unit. Each softening basin/unit has a design capacity of 18 mgd. Low lift pumping limitations, flow control to the basins, and fluctuating demands have made it difficult for WTP staff to stabilize the softening process. Softening is accomplished by feeding lime. The decision was made by the City not to feed soda ash in order to remove non-carbonate hardness because acceptable hardness levels could be achieved with lime feed only and softening is short term until Lake Huron water becomes available.

7. Recarbonation
Recarbonation for pH adjustment is accomplished in east and west recarbonation basins between and to the north of the softening basins. Carbon dioxide storage and feed equipment is located west of the recarbonation basins.

8. Filtration
Filtration is accomplished with 12 dual media filters, equally sized and designed to filter 3.0 mgd each. Media consists of 12" of sand and 18" of anthracite. The filters have been operated intermittently over the years due to the standby nature of the WTP and until recently, chlorine injection took place downstream of the filters. It is possible some microbial growth has developed in the filters.

9. Disinfection
Limited disinfection is provided by ozonation, but the primary form of disinfection is chlorine fed prior to filtration and prior to finish water storage / high service pumping. The intermediate chlorine injection location was recently constructed under the Phase II, Segment 1 contract.

10. Clear Well & Pumping
The pump building sits adjacent to a 3 MG clear well and contains both low and high service pumps.

8. JAR TESTS / EXPERIMENTS

1. Approach
There are several well practiced methods by which DBPs can be reduced. First, the disinfectant can be changed to an alternate that has a lower tendency to form DBPs. Second, additional treatment systems such as activated carbon or air stripping (depending on the nature of the precursors) can be added to remove DBP precursors. Lastly, the existing treatment processes can be optimized to remove as much DBP precursor as possible. Of these options, optimizing existing treatment processes is the only strategy that does not require the construction of new and expensive facilities. It is anticipated that Flint will be receiving Lake Huron water in approximately two years and this water will have a completely different chemistry from the Flint River. Major process changes instituted to address THM levels using Flint River water are likely to be unnecessary for Lake Huron water and may even be inappropriate. Therefore, those options which require addition of new treatment processes are undesirable at this time. In recognition of this upcoming change in water source, this study will concentrate on improving the existing processes, rather than adding new ones. New treatment processes will only be recommended if operational changes to the existing treatment train prove ineffective.

Recent sample test results suggest that most of the DBPs are formed in the distribution system rather than within the treatment plant. Therefore, the most logical approach is to reduce the DBP formation potential (DBPFP) rather than simply lowering the levels of DBPs leaving the plant. During bench scale testing, formation potential (FP) levels will be the primary indicator of success or failure of any proposed process modifications.

2. Protocol
Bench scale pilot testing is intended to reflect actual plant operating and hydraulic conditions so the bench scale treatment units will be sized based on various dimensionless factors to ensure the pilot treatment matches the actual system. Bench scale ozonation is not practical due to time and cost limitations. Therefore, water

samples will be withdrawn following the plant ozone basin. These samples will be transported to the laboratory where they will be dispensed into square testing jars. The jars will act as rapid mix, three-stage flocculation, and settling. Rapid mix and flocculation conditions will be matched to the plant based on "Gt" values. The "G" value is a measure of the mixing intensity and is a function of mix time, viscosity of the liquid, and mixing power applied to the water. "Gt" then, is a size scaling factor where time has been accounted for. Settling time will be scaled to match the shorter settling depth of the testing jars. After settling, samples will be decanted from the test jars. The decanted samples will then be lime softened; softening conditions will be similarly matched on the basis of "Gt". Fluoride will be added and carbon dioxide sparged into the samples to reduce the pH. The water will then be vacuum filtered through filter paper, sized to simulate the plant's dual media filters. The samples will be dosed with excess chlorine and allowed to react for seven days before testing for DBPs to determine the formation potential.

Although these conditions may be refined based on new information, we anticipate the following:

TABLE 4 – BENCH SCALE TEST MIXING INTENSITIES

Process	G	Duration
Ozonation	Plant	-
Rapid Mix	330	25 sec
Flocculation, Stage 1	50	9 min
Flocculation, Stage 1	25	9 min
Flocculation, Stage 1	12	9 min
Settling	na	10 min
Softening	TBD	10 min
Recarbonation	na	na

It is expected that the primary variables during the testing will be chemical additions and chemical dosages. Specific chemicals and dosages used for initial testing conditions will be selected to reflect current plant usage and the recommendations of the 2002 Treatability Study.

TABLE 5 – BENCH SCALE TEST CHEMICAL FEED RATES

Chemical	Current Usage	2002 Study
Ozonation	4.66 mg/l	1.5 mg/l
Ferric Chloride	7.7 mg/l	40 mg/l
Coagulant Aid Polymer	Not used	2.0 mg/l
Flocculation Aid Polymer	Not used	0.05 mg/l
Lime	120 mg/l	175 mg/l
Soda Ash	Not used	52 mg/l
Cationic Softening Polymer	3.13 mg/l	Not used
Anionic Softening Polymer	0.88 mg/l	Not used
Fluoride	0.45 mg/l	1 mg/l
Carbon Dioxide	32 mg/l	37 mg/l
Chlorine	6.3 mg/l	1 mg/l

3. Considerations

The 2002 Treatability Study did not note significant formation of DBPs. This may be a function of different Flint River water chemistry at that time. However, recognizing the considerable differences in chemical usage and dosages between that study and current operations, those differences in chemical use and dosage are an obvious starting point for optimizing treatment to prevent DBP limit exceedance.

Although it is believed that optimization of current treatment can correct the DBP issue, should optimization of present treatment prove insufficient, alternate residual disinfectants (chloramines and chlorine dioxide) will be investigated as additional treatment measures.

4. Results

[To be completed following jar testing and experimentation]

5. Conclusions

[To be completed following jar testing and experimentation]

DRAFT

IV. DISTRIBUTION SYSTEM EVALUATION

EPA guidance for the distribution evaluation portion of an OER is focused on identification and isolation of a specific portion of the distribution system that led to the exceedance. The circumstances of Flint's apparent pending TTHM exeedances are unusual in that a new supply has been implemented which clearly corresponds to the high TTHM sample results. Despite obvious implications to the primary cause of increased TTHM levels, value remains in evaluating the distribution system as there may still be distribution improvements that can be made to help alleviate the problem.

Evaluation of the distribution system, including modeling, was recently added to LAN's scope of services. When finished, information will be provided to complete the following topics in this section.

A. INFRASTRUCTURE

1. Piping

According to the most recent MDEQ Sanitary Survey, the distribution system is estimated to contain 70% cast iron, 20% ductile iron, 2% concrete and 8% steel water mains. Unlined cast iron pipe can become pitted, allowing colonization sites for microorganisms leading to chlorine demand. Additionally, much of the piping in the system is aged and in poor condition. Increased chlorine demand could be resulting from biofilm in older pipes and from main breaks/repairs.

The City utilizes City Point software and GPS equipment to document main breaks and prioritize replacements. Areas that have been targeted for main replacements include Fenton Road, Atherton Road, Dort Highway, Averil Street, and Boulevard Drive. The extent of contribution is not known but any water main replacement project will contribute to decreasing chlorine demand somewhat if constructed properly.

2. Storage

[To be completed]

- *Appropriate capacity*
- *Mixing, baffling, other provided to prevent stagnant water*
- *Condition*

3. Pump Stations

[To be completed]

- *Condition*
- *Pump capacity evaluation*
- *Valve condition and pressure zones*

B. OPERATIONS AND MAINTENANCE

1. Pump Station & Storage Operations

[To be completed]

- *Control of pressure districts*
- *WTP Pump Station (No. 4)*
- *Cedar Street Pump Station*
- *Westside Pump Station*

DRAFT

- *Torrey Road Pump Station*
- *High and low levels in tanks*

2. Booster Disinfection Practices

Booster disinfection is provided at the Cedar Street and Westside pump stations. Sodium hypochlorite is applied while the reservoirs are being filled.

3. Changes in System Demands

[To be competed]

- *Long term decline in demands*
- *Short term fluctuations – max day in winter due to high volume of main breaks*

C. WATER SYSTEM HYDRAULIC MODELING

[To be completed]

1. Simulation of Existing System

Match existing conditions, particularly chlorine residual. We have chlorine feed data at plant and residuals at 10 locations in each MOR, May-October.

2. Identification of Deficiencies

Specific issues to look at:

Worst case at minimum daily demands
Water age in entire system
Recirculating water through pump stations
Use of storage tanks
Indications of broken valves
Effectiveness of booster disinfection

DRAFT

V. RECOMMENDATIONS TO MINIMIZE FUTURE OEL EXCEEDANCES

A. SOURCE

The City of Flint has already committed to the change from the Flint River as the water source to Lake Huron under the KWA system, planned for late 2016. The risk of future TTHM limit violations will decline substantially with the use of water from Lake Huron due to much lower DBP precursors. It is important to recognize that the Flint River will become strictly an emergency supply when the KWA supply becomes available and any investments toward the Flint River should be contemplated accordingly. Recommendations discussed below in this section apply to the Flint River as the source.

Reverting to supply from the DWSD until the KWA supply is available as an option. However, the DWSD has stipulated that a $4 million connection fee would apply and current water rates would include approximately $900,000 / month flat fee plus usage charges. Therefore, utilizing the DWSD for interim supply is cost prohibitive under the terms defined by the DWSD.

1. Watershed Management

A volunteer group entitled the Watershed Coalition performs various tasks related to managing the Flint River watershed such as spring cleanups and annual benthic studies to evaluate the river 'health'. No additional action is recommended at this time.

2. Monitoring

The City documents typical raw water characteristics as part of standard preparation of Monthly Operating Reports (MOR). No changes are recommended at this time.

3. Intake Operations

The 2002 Treatability Study recommended pre-oxidation in the form of sodium permanganate as a feed at the intake. However, pre-oxidation with sodium permanganate is unlikely to provide significant oxidizing of organics beyond that provided by ozonation. It is possible the addition of hydrogen peroxide would enhance the ozone process.

4. Seasonal Strategies

Past data indicates the Flint River is influenced by groundwater and in particular, dolomitic spring water. The result is hard water with high concentrations of magnesium and sulfate. Also, hardness and alkalinity are higher during the winter. Upon initiation of supply from the Flint River, the City made the decision to soften with lime only to focus on removal of carbonate hardness. One potential modification that could assist with TOC removal and thus decrease THMFP would be lime and soda ash softening. If implemented soon, the procedural change would be timely as it would also address increased hardness expected going into this winter.

5. Upstream Contamination Issues

Upstream contamination issues are extremely difficult to prevent and even if detected are difficult to locate. Evaluation of raw water data collected for MORs is the easiest manner in which to detect upstream contamination issues because the data is already collected for treatment purposes. In fact, high total Coliform readings signaled a potential issue recently that the City identified and removed.

An upstream monitoring and warning system could be established to attempt to detect spill event type contamination early enough to cease intake prior to the

contamination reaching the WTP. However, given the imminent conversion to the KWA supply, the period of full time use would likely be far too short to achieve payback on the capital expenditures.

B. TREATMENT PROCESS

1. Operational Recommendations

- Coagulation and flocculation polymer aids: The 2002 Treatability Study suggested the use of coagulation and flocculation polymer aids. These polymer aids were shown in the 2002 Treatability Study to increase TOC removal and thereby reduce THMFP. Further evaluation will be completed during jar testing.
- Discontinue softening bypass: The City was previously bypassing a portion of flow around the softening basins because hardness levels did not warrant softening of the full stream. However, this practice was discontinued because it was believed the bypass stream was contributing to chlorine demand and preliminary data has supported that belief. Chlorine demand dropped 0.5 – 1.0 mg/l following elimination of the bypass stream in early November 2014.
- Soften with lime and soda ash: Research has shown that enhanced softening with both lime and soda ash may provide additional TOC removal. The efficacy of this option will be evaluated during jar testing.
- Disinfection of filter beds: In case there has been microbial growth it is recommended the filters be 'shock' treated with chlorine and rinsed. A chlorine injection point was added upstream of the filters during the first segment of Phase II so future growth in the filters should not be an issue.
- Optimization of all existing treatment processes: Depending on bench scale testing conditions and results, slight modifications to all treatment processes might in order to replicate lower DPBFP.

2. Infrastructure Change Recommendations

- Fix and/or replace faulty ozone equipment: Since the ozone equipment was installed it has not been used extensively so the hope is that major components remain in good condition and the system can be easily modified to restore proper functionality. The City has scheduled the equipment manufacturer to field inspect the system on December 15, 2014.
- Change disinfectant to chloramine or chlorine dioxide: If other options prove to be ineffective, conversion to another disinfectant should be fully evaluated. Various characteristics of chloramination indicate an advantage over chlorine dioxide, but a full analysis would provide clarity as to which would be preferred.
- Install pre-oxidant chemical feed: Hydrogen peroxide as a pre-oxidant can enhance the activity of the ozone. This option is listed as a consideration only if problems continue with ozonation.
- Repair upstream sewer leak: a sewer leak upstream of the WTP intake was discovered and has already been repaired by the City.

C. DISTRIBUTION SYSTEM

Recommendations will be incorporated into this report when available. It is anticipated details will be provided for the following topics. [To be completed]

1. ***Manage Water Age***
   a) ***Storage Tanks***
   b) ***Residence Time in Pipes***

2. ***Reduce Disinfectant Demand***
   a) ***Flushing***
   b) ***Cast Iron Pipes***

3. ***Water Modeling of Recommendations***

Determine best flushing locations to reduce water age
Changes to storage tank operating levels to reduce water age
Valves to close/add to improve pressure zones, reduce recirculation
Optimization of pump station use – smaller pumps? Shut down?
Evaluate booster disinfection

A number of actions have already been taken in terms of the distribution system. Water main flushing efforts were increased until late November when freezing weather became prevalent. Also, numerous valves that were broken in the closed position and believed to have been contributing to stagnant water were replaced.

D. BOOSTER DISINFECTION

Decreasing chlorine feed at the WTP and adding booster disinfection in the distribution system is an alternative intended to reduce the reaction time at higher concentrations of chlorine to reduce DPB formation. Extensive looping and branching within the existing system complicate how to best implement and utilize booster disinfection. Water system modeling is recommended to determine the most effective feed point locations and dosages. Further discussion and details will be provided when the distribution evaluation results are available.

E. CATEGORIZATION OF ACTIONS

Considering that the Flint River is being used as the water source only until the KWA supply is available (expected late 2016), options to address high THM formation that require new construction or extensive time to implement are not preferred. On the other hand, the City understands THM sample results to date dictate that some action is necessary. Two categories have been developed to assist the City in prioritizing actions to take. Stage 1 consists of actions that can be completed relatively quickly without major construction and Stage 2 actions are either long term actions or solutions requiring major construction. Stage 1 actions are to be completed first followed by evaluation of the results prior to consideration of Stage 2 actions. Grouping of actions are shown in the table below.

TABLE 6 – ACTION PLAN		
	Action	Purpose
Stage 1	Troubleshoot ozone feed system	Reduce chlorine feed and increase TOC removal
	Bench scale jar testing	Optimize treatment process and evaluate possible modifications
	Discontinue softening bypass	Reduce chlorine demand
	Disinfect filters	Reduce chlorine demand
	Increased water main flushing	Reduce water age / stagnant water
	Water system modeling evaluation	Determine areas with high water age and reasons
	Implement coag. & floc. polymer aids, if appropriate	Increase TOC removal
	Modify booster disinfection feeds, if appropriate	Decrease water age
Stage 2	Repair ozone system	Reduce chlorine feed and increase TOC removal
	Continue increased water main flushing	Reduce water age / stagnant water
	Convert to lime and soda ash softening	Increase TOC removal
	Continue valve replacements based on water model	Reduce water age / stagnant water
	Change disinfectant to chlorine dioxide	Reduce THMFP
	Install pre-oxidant feed at intake	Optimize ozone disinfection, reduce chlorine
	Place priority on replacing cast iron water mains	Reduce chlorine demand

Samples were taken the week of November 17th for the 3rd quarter of testing. Although the City has begun implementation of Stage 1 actions, THM results are not expected to be noticeably affected since there has not been enough time for a response. The next quarter of sampling is due to be completed the third week in February. It is the City's intent to implement Stage 1 actions prior to the 3rd quarter of THM sampling.

TTHM Reduction
Action taken by City
December 16, 2014

Flint's 3rd quarter of TTHM monitoring (Nov 20th, 2014) shows a reduction in TTHM levels at all of the sampling locations. The reduced TTHMs are the combined result of seasonal variation of total organic carbon (TTHM precursors) in the raw water and action taken by the city towards reducing TTHM levels. The amount of reduction contributed by each factor cannot be determined; however, the following is a list of proactive measures taken by the city in their effort to reduce TTHM levels.

1. **Removed the 20 MGAL Dort Reservoir from service.**

   The reservoir allowed treated water from the WTP to re-circulate back to high service thus adding up to one week of retention time.

2. **Softening 100% of the WTP flow during normal plant operation.**

   Softening the complete flow reduces the chlorine demand. During high water demands (large main breaks, filling reservoirs), split treatment must be utilized due to VFD control problems with the 20 MGD low service pump; however, this is not the main mode of operation.

3. **Improved turn-over of water in distribution system reservoirs.**

   The operating range of the Cedar Street and Westside reservoirs was increased from 1-2 ft. (summer) to approximately 10 feet. The increased drawdown has reduced the residence time and improved chlorine residuals.

4. **Established a more proactive flushing program.**

   Increased flushing helped to reduce residence time in the distribution system and, especially, at dead-ends.

5. **Optimizing Transmission System Operation w. repair of major valves and confirming proper valve position.**

   Several critical valves were replaced on one of Flint's four major transmission mains and several other valves (found to be closed) were opened. This eliminated stagnation problems in areas near this main, improved chlorine residuals and allows the main to operate in a looped configuration.

Action to be taken soon:

- **LAN treatability study – jar testing (Starting this week)**
- **Trouble shoot Ozone system – early January**
- **Disinfect filters – after the next "top-off" of system reservoirs**

Subject: Flint Drinking Water Actions

Brad,

Here are some of the actions Flint has been taking to address the TTHM levels.

1. Removed the 20 Million Gallon Dort storage reservoir from service to prevent stagnant water conditions.
2. Softening 100% of water instead of partial softening to reduce amount of chlorine needed
3. Modified operation of water storage tanks to increase turn over and reduce stagnant water volumes.
4. Increased frequency of water main flushing to reduce detention time and stagnant water conditions.
5. Repair transmission water mains and valves to allow direct flow patterns and reduce detention time.

The City is also working on these additional items:

1. Further optimization of the enhanced coagulation process, possible use of polymer chemicals
2. Optimization of the ozone treatment process
3. Enhanced cleaning of filters to help reduce amounts of chlorine needed for disinfection

Mike Prysby can provide additional information as needed.

DBP Sampling Frequency – 8 samples quarterly

- Routine samples are collected during the 3rd full week of February, May, August, & November.
- Prior to April 2014, four (4) samples were required under EPA Stage 2 DBP. Those sites are included in our current 8 samples, and are changes in site codes are indicated in red.
- Due to initial high levels of TTHM after full time operation in April, extra samples have been collected from our Cedar St. & West Side pump stations/reservoirs, to help us determine beneficial operational procedures.

Attachments: Nov 2014 MOR Scan.pdf; DBP Distribution System Sampling Site Locations.docx

Mike,

Good afternoon. I don't believe we sent a formal copy of our DBP monitoring plan to reflect the change for full time operation. Prior to April 2014, the Stage 2 DBP monitoring sites were: DBP 1 - 3719 Davison Rd, DBP 2 - 3302 S. Dort Hwy., DBP 3 - 6204 N. Saginaw St., DBP 4 - 2501 Flushing Rd. After April, our monitoring schedule showed that we had to collect 8 DBP samples quarterly. With only 8 distribution sites (disregarding the reservoirs) we use every site in Bacteriological Sample Site Plan. Site #1 is now DBP 1, Site #2 is now DBP 2, an so on. We continued on the same sample time schedule as before April: The 3rd full week of February, May, August, & November. I have attached a copy of the "rough" DBP sample monitoring plan.

I have also attached a copy of the November 2014 MOR, a hard copy will be sent out today.

TTHM Media Inquiry
January 5, 2015

I received a media inquiry from Ron Fonger of the Flint Journal concerning the TTHM MCL violation in the city of Flint. Ron was provided with a copy of our December 16, 2014 Violation Notice letter to the city of Flint concerning the TTHM violation. Ron was also provided with a draft press release on Jan 4th concerning measures being taken by the city to address the TTHM violation. Below is a summary of the questions asked by Ron and my response.

- **How common are TTHMS in Michigan and are there other systems in violation?**

  TTHMs are found in systems that disinfect with CL2 due to the reaction between CL2 and naturally occurring organic compounds (total organic carbon - TOC) in the raw water. There is one other system (customer supply of Saginaw) that has exceeded the TTHM standard. Since this is outside of my district, I do not know the details of the violation.

- **How widespread are the high TTHM levels in Flint?**

  TTHM is monitored at 8 locations throughout the city. Compliance is based on a Locational Running Annual Average (LRAA) meaning that any one location will put the city out of compliance with the TTHM standard if that location fails to meet the standard based on the running annual average (RAA) of 4 quarters of monitoring. The LRAA was exceeded in just 3 quarters at two of the eight locations due to high TTHM concentrations at these locations(May and August quarters).

- **What level of concern should city residents have?**

  TTHMs are a health concern associated with long-term (chronic) exposure as opposed to other contaminants such as pathogenic organisms (fecal coliform, giardia, crypto, etc.) which are short-term concerns…ie…immediate impact to public health. The potential health effects provided in the notice are possible with

long term exposure over a significant portion of the person's lifespan. Consumption of drinking water with TTHMs at this concentration does not pose an immediate threat to public health.

- The most recent test results (November) appear much better; what do residents need to know for the future?

  The decline in TTHMS is two-fold. First, the decline is the result of the city taking pro-active measures in collaboration with the DEQ to address the TTHM concentrations that includes: optimizing current treatment, shortening residence time in water storage reservoirs, optimizing ozone treatment, and improving operation of the distribution system (flushing, repairing valves, and opening valves to eliminate areas of stagnation).

  Next, seasonal variation also contributed to the reduction in TTHM levels as the TOC loading from the Flint River watershed diminishes during the winter months. T

  The city is also pursuing additional treatment options (enhanced coagulation) to help remove TOC and filter cleaning to reduce CL2 demand. Hydraulic modeling of the distribution system will also be performed to further optimize operation of the system reservoirs and pumping stations aimed at reducing stagnation. These efforts combined with steps already taken are expected to dampen higher TTHM levels during the 2015 summer months.

- There has been some criticism regarding the timing of the notice…ie…why weren't residents notified during earlier when high TTHM results were being obtained?

  The city was not in the position to provide a notice since the results obtained last summer did not place the city into a violation status. Also, since TTHMs pose a health concern with term-term exposure ….and in anticipation of exceeding the standard by the end of 2014, the city elected to pursue a proactive approach towards reducing TTHMs (treatment & distribution operation). The city also worked with the DEQ in this effort along with preparation and distribution of the mandatory public notice within 30 days of the start of the violation (December 1, 2014). I

also explained how the LRAA is calculated and why the first two quarters did not constitute a violation.

- **What triggers the TTHM violation?**

As mentioned above, if exceedance of the LRAA (based on 4 quarters of results) occurs at ANY of the eight sampling locations the city is in violation. The LRAA can also be exceeded in less than four quarters (based on a 4-quarter calculation) if the concentration is high enough.

Flint NBC 25 News Interview
Flint TTHMs
January 5, 2015

Walter-Smith Randolth, reporter, from Flint NBC 25 News conducted a telephone interview with me for broadcast on Flint local television concerning the TTHM violation in Flint's drinking water. I led the interview and provided Mr. Randolth an opportunity for follow-up questions. Below is a summary of topics that were presented.

<u>TTHM violation – What does this mean for Flint residents?</u> The TTHM violation notice to residents is not an immediate public health emergency since the health-effects posted in the notice require long-term exposure to TTHMs (over a significant portion of an individual's lifespan). TTHMs commonly occur in public water systems that disinfect with chorine due to the reaction between chlorine and naturally occurring organic compounds (total organic carbon) in the source water. Surface water sources, including the Flint River watershed, typically have higher levels of naturally occurring organic compounds.

<u>What is the DEQ's Role?</u> The DEQ is working in collaboration with the city to ensure long-term public health protection and to keep the public informed. We are working with the city to help identify improvements in treatment and operation of the distribution system to reduce the levels of TTHMs. We are assisting the city with public notice requirements (when to post/contents). With our assistance, the city has proceeded with an operational evaluation of the water system ahead of state and federal requirements.

<u>DEQ's perspective of the situation:</u> The Flint River source is more difficult to treat since it requires more disinfection to maintain bacteriological intergrity. Increased disinfection; however, when combined with higher levels of naturally occurring organics results in elevated levels of TTHMs that form over time out in the distribution system. The TTHM concentrations that developed in the system were more than anticipated due to several reasons:

1. **Flint did not immediately change their mode of distribution system operation after switching sources to account for higher TTHM formation potential of treated water from Flint's WTP.**

I explained that TTHMs require time to form and are not fully developed in the treated water that enters the distribution system from the WTP. Water from Detroit; however, is several days old when it reaches Flint; thus the majority of the TTHMs are developed. TTHMs were also lower given the source water (Lake Huron). Flint's historically operated the distribution system in a manner that created conditions favorable for stagnation. This methodology of operation was not changed (initially) when switching to the Flint River; thus, this condition was one of several factors contributing to higher levels of TTHMs. Other factors included; higher TTHM formation potential in the Flint River (already explained above) and higher chlorine application rates at treatment plant to maintain bacteriological integrity.

I further explained that TTHM levels in the most recent quarter have dropped for two main reasons:

1. **Action taken by the city including; improving dist. system operation to reduce stagnation, treatment changes (complete softening), reduced chorination, system flushing, valving improvements**

2. **Seasonal fluctuation of organic compounds in the Flint River. Less organic loading in the winter months.**

END of MY DISCUSSION

Mr. Smith-Randolf asked for my comment to the following questions/statements....Why this problem is occurring in Flint? Is there a problem with the water system? This was not an issue when Flint was on Detroit water.

I responded by summarizing some of the key points discussed above including:

- **Dist system operation (storage facilities and valving)**
- **TTHM formation potential in Flint River vs. Detroit and age of incoming water**
- **High chlorine dosages to maintain bacteriological integrity**
- **Treatment practices at WTP (partial by-pass of softening)**

  - to say SAFE OR UNSAFE is not as definitive as a
- Not pot. Health
  - Not on immed. public concern since TTHMs are a based on chronic (long-term) exp.
    - short term exp. to long-term contaminant has diff impact on each indiv based on their background → Med. issue prev. exposure
    - Each indiv is different & if concerned should seek advice w. Health care provider to take steps to ↓ risk

Meeting with Rep. Neeley and Rep. Phelps
Flint TTHMs
January 6, 2015

Richard Benzie, Sarah Howes, and I met with State Representatives Sheldon Neeley, 34th District and Phil Phelps 49th District to discuss the TTHM violation in Flint's drinking water. Several follow-up questions were asked during and after our discussion. Information provided to Mr. Neeley and Mr. Phelps was in a format similar to that provided in the NBC-25 News interview. We focused on:

What does the TTHM violation mean for Flint residents?

The violation does not pose an immediate public health threat since the health-effects requires long-term exposure to TTHMs (over a significant portion of an individual's lifespan).

TTHMs commonly occur in public water systems that disinfect with chorine due to the reaction between chlorine and naturally occurring organic compounds (total organic carbon) in the source water.

Reason(s) for the violation:

The Flint River source is more difficult to treat since it requires more disinfection to maintain bacteriological integrity; however, this leads to more TTHM formation.

Flint did not immediately change their mode of distribution system operation after switching sources to account for higher TTHM formation potential of treated water from Flint's WTP. Historically, their mode of operation created areas of stagnation in the distribution system which then contributed to the higher levels of TTHMs.

Ongoing Efforts:

The city is working in collaboration with the DEQ towards identifying improvements in treatment to remove TTHM precursors and optimize distribution system operation. The city has already taken action on some of these measures including: complete softening to reduce chlorine dosage and increased turnover of water in the distribution system storage reservoirs to

reduce stagnation. The city is also correcting valving deficiencies to further reduce stagnation.

The city has received scrutiny on the perceived delay to inform residents of the high TTHM levels; however, we stressed that the city has met the state and federal requirements for public notification of this particular contaminant. We explained the rational for determining compliance with the TTHM standard and how this correlates to the public notification requirements. We also informed Mr. Neeley and Mr. Phelps, that TTHM compliance is determined on a RAA (based on 4 quarters); thus, the city will likely remain in violation even with one or two subsequent quarters producing results that are below the MCL.

We also suggested, in addition to meeting our public notification requirements, it may be helpful for the city to explain to their residents how compliance with TTHMS is determined and, more importantly, keep them informed (snapshot in time) of each quarter's results (regardless of compliance status).

Result of On-going Efforts

Efforts taken by the city resulted in a significant reduction of TTHMs in the November 2014 quarter. Seasonal fluctuation of organic loading in the Flint River watershed (less loading in the winter months) also contributed to lower TTHMs.

Questions that were asked:

Can the State become involved with additional TTHM monitoring (third party monitoring)? How would the cost be covered?

The city may elect to conduct additional TTHM monitoring; however, this would be at the city's expense. DEQ staff, depending on availability, may be able to assist in the monitoring. Additional monitoring could be eligible as part of future compliance calculations; however, the monitoring protocol must be approved by the DEQ.

Are the operators at the Flint WTP properly certified?

Yes. The city has an F-1 operator, Mike Glasgow who oversees treatment

operation and is the designated OIC. There are also several F-2 operators including Brent Wright (WTP Supt.). The city has also hired additional operators for full-time plant operation. Many of these operators acquired their F-4 certification last fall.

Public Forum

Wednesday January 21, 2015
7:00 pm City Hall Dome

AGENDA

Opening COF – DPW Director - Howard Croft

- Forum Ground Rules (disorderly conduct will not be tolerated)
- Overview of Format (each guest to speak for ~10 minutes with written questions afterword)
- Recognition of Officials
- Introduction of Guests

1st Speaker DEQ – Local Representatives - Mike Prysby, Steve Busch

- Role of DEQ
- Explanation of TTHM violation

2nd Speaker LAN – Lead Engineer - Warren Green

- Discuss Engineering role
- Discuss Operational Evaluation Report

3rd Speaker MSU Microbiologist – Dr. Joan Rose

- Risk Assessment (what do the numbers mean?)
- What to do if someone suspects they are at risk
- What about the elderly and those with a weak immune system
- What will the next violation mean (water is still safe)

4th Speaker GCDC – Jeff Wright

- What to expect from KWA raw water as source
- Update on KWA timeline

Final COF – DPW Director – Howard Croft

- Summary (Next Steps – Action Plans)
  - Hiring an industry expert
  - Tours of Treatment Plant
  - Continued communication
  - Planned steps (CIP built on , Water Reliability Study, Operational Evaluation Report)
  - Funding (researching all sources, state funding, federal opportunities)
  - Water & sewer rates (budgetary evaluation upcoming)
- Questions (Expected to have an hour of panel response time)
- Conclusion - Thank the panel, (Additional follow up at next Public Works Committee meeting)

Department of Environmental Quality (DEQ)

Michael Prysby, P.E.
District Engineer

Stephen Busch, P.E.
Lansing and Jackson District Supervisor

Lockwood, Andrews, and Newnam (LAN)

J. Warren Green, PE
Senior Associate, Director of Engineering

Warren has more than 30 years of experience in engineering management and supervision of complex water treatment and transmission facilities projects. He has successfully guided water system improvements through all necessary phases including feasibility studies, pilot testing, design, financial evaluation, land acquisition, construction, start-up and operation. His expertise is in the areas of facilities design, construction management and contract administration.

He has worked with several municipal utility clients throughout Illinois, Mississippi, Michigan and Wisconsin. He worked with the Green Bay Water Utility in Green Bay, Wis., for 12 years, serving as a project manager for a number of design and contract administration tasks. These included the expansion of a 10-mgd raw water pumping station, construction of approximately 17 miles of 54-in. steel water transmission main, and expansion of its water treatment plant in 1997 and 2004. He also oversaw a $376 million project in DuPage County, Ill., where he was responsible for contract administration and construction management of 140 miles of water transmission mains.

MSU Water Quality and Environmental Microbiology Laboratory

Dr. Joan B. Rose, Ph.D.
Laboratory Director/Principal Investigator
Homer Nowlin Chair in Water Research
Co-Director Center for Water Sciences
Co-Director Center for Advancing Microbial Risk Assessment

Joan is an international expert in water microbiology, water quality and public health safety and is a member of the National Academy of Engineering. She has been involved in the investigation of numerous waterborne outbreaks world-wide. Her work addresses the use of new tools for surveying and mapping water pollution for recreational and drinking water; assessment of water treatment technology and use of risk assessment.

Degrees:

- Bachelor's (1976) and Ph.D. (1985), microbiology, University of Arizona
- Master's (1980) microbiology, University of Wyoming

Genesee County Drain Commissioner

Jeff Wright

Past positions include:

- Chief Executive Officer of Karegnondi Water Authority
- Legislative Committee and Executive Board of Michigan Association of County Drain Commissioners
- Northeast District Chairman – Michigan Association of County Drain Commissioners
- Former Secretary/Treasurer – Michigan Association of County Drain Commissioners

Community Water Supply

Information Regarding

Total Trihalomethane (TTHM)

Disinfection Byproducts

(1)

DEQ - Community Water Supply

- Regulatory Authority over Public Water Systems
- Michigan Safe Drinking Water Act (Act 399) – Adm Rules
- 1400 Community Supplies in MI (like Flint) Eg. Unique, RAW well cust
- Lansing Jackson Districts – 300 in 13 counties source Dist
- Oversight through:
  - Inspection Visits/surveys
  - Monitoring – Provide Stds – Treatment Dist. → T1 H M
  - Construction Permitting – Review/Approve design → Act 399 permit
  - Planning – 5yr/20yr needs – R.S./DWRF
- Partnership and Compliance Assistance
  - DEQ works collaboratively w. PWS on solutions to correct WR Problems
  - We assist w. compliance on the Alternative chosen by the PWS

What are TTHM's

Trihalomethanes occur when natural organic matter in the water react with chlorine disinfectants. (Byproduct of disinfection process)

4 Chemical Compounds made up of these elements:

- Carbon
- Hydrogen
- Bromine
- Chlorine

Form the 4 main Constituents of TTHMs →

Bromoform
Chloroform
Bromodichloromethane
Chlorodibromomethane

Bromo-Di-chloromethane
Chloro-Di-Bromomethane

TTHM Standard

Not An Acute Pub. Health Concern that Microbial contam. poses

- Based on chronic exposure to low doses
- 80 parts per billion (0.080 ppm) – will be ref. in next slide
- Locational Running Annual Average (LRAA) ← compliance is BASED ON
- Quarterly monitoring at each location ← conducted on
- Location and timing based on highest risk — Longest res time in syst.
- Running = over last 4 quarters, not calendar yr
- Total sum of 4 quarters not to exceed 320 ppb → See table

→ Dist Mon./Not @ WTP due to disinf. byprod. whose conc. varies (↑) with travel time in dist.

Private Avg 15 Administrative Ruling

O_3 system Repaired & up & running good

100% softening – Every 5 hr running

KMnO4 – Also – Use last & d. pre/post T.C

Stage 1 – Immediate Actions

- Hire ozone system manufacturer to troubleshoot ozone system
  - Manufacturer and controls programmers have performed on site evaluations
- Bench scale jar testing
  - Match existing process and assess possible areas of improvement
    - Existing process simulated, evaluation of existing chemical feed dosage adjustments partially complete
  - Simulate potential modifications to treatment process
    - Soda ash softening evaluation partially complete, PAC feed yet to be tested
  - Evaluate coagulation and flocculation polymer aid feeds to assist with TOC removal
    - Evaluation of polymer aids partially complete
- WTP operational changes
  - Discontinue softening bypass stream to reduce chlorine demand
    - Operational directive has been set to soften no less than 90% of flow
  - Disinfection of filter beds to reduce chlorine demand
    - Utility Service Group has been contracted by City and condition assessment is currently underway
  - Possibly begin coagulation and flocculation polymer aid feeds to assist with TOC removal depending on bench scale test results
    - Polymer aids still being evaluated, but increased ferric dose implemented
- Increase water main flushing efforts to minimize stagnant water
  - Flushing efforts ongoing
- Water system modeling to identify areas with high water age and potential solutions
  - Cedar Street Pump Station potential recirculation
  - West Side Pump Station potential recirculation
  - Storage tank volume use
    - Increased reservoir output to reduce detention time
  - Possible broken closed valve locations
    - Model has been updated with known broken valve locations. Model results are being evaluated for indications of other possible broken valves. City has also initiated valve assessment program.
  - Locations in need of flushing
    - High water age areas have been identified in the water model. Further evaluation forthcoming to determine most effective flushing points.
  - Lower high water levels in storage tanks
    - Operating levels of all reservoirs have been lowered to reduce water age

Stage 2 – Contingent Actions

- Fix ozone system
  - Some repairs have been made to gauges and programming and the system is producing adequate ozone. Cleaning and additional minor repairs are forthcoming.
- Start feeding coagulation and flocculation polymer aids to lower TOC, if not completed in Stage 1

    - Alternative comparison and cost effectiveness being evaluated
- Convert to lime and soda ash softening
    - Alternative comparison and cost effectiveness being evaluated
- Change disinfectant to chloramine or chlorine dioxide until KWA
- Install pre-oxidant feed at intake to optimize ozone disinfection
- Implement advanced treatment for THM precursor removal
- Increased main flushing based on water modeling results
- Continue valve replacements with water model assistance
- Emphasize cast iron pipes on water main replacement priority list

Subject: Technical Advisory Committee Update

Team,

I have include a list of all of the current participants in the Technical Advisory Team. We are targeting Wednesday March 4th as the first meeting and the time and place are yet to be determined. I have listed a few items to help craft the direction that we are hoping to go with this team;

1. We will likely have a conference number as well as a physical meeting place in case someone is not able to be there.

2. We will define as we go along how often to hold meetings, but we plan to continue throughout the implementation of the KWA.

2. We will start with a general scope and set of deliverables but will look for open input from the group in order to develop additional specifics as to what each member would like to accomplish.

3. Certainly with this assembled team we would want to develop a set of medical FAQ's that would assist the medical community with current and future details of chemicals and risk assessments.

4. We will discuss the treatment process and look at the national discussion on whether or not to use fluoride as well as what additional regulations are possibly being considered the EPA for the future.

5. We will look at what is upcoming with the KWA and water from Lake Huron. What will the chemical challenges be? What will the final product entail?

6. We will evaluate testing options or partners and determine if there is an avenue or demand for such.

These are some of the topics that I plan to delve into and I believe that we have assembled a professional team that can bring enlightenment to all of us. I look forward to working with each of you.

Respectfully Submitted,

Subject: Re: call

Mike

Marvin Gnagy from Veolia wanted to talk with you about some of the suggestions they were making for treatment here at the plant. He wanted to know what could be implemented right away and what might need permit approval from the MDEQ. They were here running test all week but left yesterday. I have listed his contact number and email below. I would appreciate it if you could get in contact with him so he can finalize his report and send his recommendations to the city administration.

Technical Advisory Committee Members,

On behalf of the City of Flint, I want to thank you for your willingness to participate in the City of Flint Technical Water Advisory Committee. This committee was formed to address many of the issues related to water that have arisen in our community over the past 10 months.

The first meeting is scheduled for Wednesday March 4th, 2015 from 2:00 – 4:00 pm at Flint City Hall. At our first meeting we will hear an overview from the engineer of record Lockwood Andrews & Newnam, and a review of the assessment findings and recommendations from our consultant Veolia North America.

We welcome the addition of a USEPA Representative that will be present at the first meeting as well as our other distinguished participants. For those that cannot be present in person we have established the ability to participate via a conference line.

For conference access please call PPI conference number PPI.

Regards,

Howard D. Croft
Public Works Director
City of Flint

Attachments: TAC Invitation Letter.pdf

Technical Team Members,

This is a reminder of our first meeting date next Wednesday March 4th at Flint City Hall at 2:00 - 4:00 pm. Please bring any questions or goals that you would like to see developed out of the group as we will create the final overarching agenda in the committee.

On a side note, our February TTHM test results were returned from the state lab this morning and all eight test sites are substantially below the MCL.

I look forward to seeing everyone on Wednesday.

Regards,

City of Flint
Operational Evaluation Report
March 1, 2015
MDEQ Comments

1. Revise Tables 2 and 3 on Page 7 to account for proper alignment of DDBP samples (results, location, site code). Also, revise statement on Page 1 regarding the number of sites exceeding the TTHM MCL following the 4th quarter sample cycle.

2. The ozone system was recently repaired. (Page 10 & 19). What is the ozone system's current production rate?

3. The city's hydraulic model (prepared by Potter Consulting) is being updated (Page 16). Is the model currently sufficient in determining proper sizing for the transmission main replacement in DuPont & Bishop Street corridor? (currently sized at 24-inch) (Pages 5, 16, and 20)

4. Are the potassium permanganate results & conclusions available? (Pages 4 and 17)

5. We agree that some reduction in storage volume could be achieved without compromising reliability; however given high usage, main breaks, and "let runs" during the winter, storage volume remains important. We agree with the need to determine adequate storage volume which will likely differ between summer and winter. (Page 15)

6. We agree with the concern of re-circulation of water pumped from the booster pump stations; however, we were recently informed of existing distribution system check valves to prevent recirculation. These appurtenances and their condition need to be confirmed. The hydraulic model may also need to be updated to include these valves. (Page 15)

7. We concur with the recommendation to provide the ability to monitor raw water TOC and PTAP TTHM. (Pages 17 & 18)

8. Page 20 provides 2 options to manage water age and each option includes reducing the utilized storage volume of the 3 MGAL well to 2 MGAL. The reduction in storage volume limits the WTP's ability to meet CT under worst case conditions (low temp, high pH, 30 MGD pumping rate from reservoir).

9. Table 11 on Page 21 outlines an Action Plan for Stage 1 and Stage 2 actions. Several actions listed in Stage 2 including; repair of ozone system, continued valve replacement, and replacement of deteriorated watermains are longer term solutions; however, they need to proceed regardless of the outcome of TTHM reduction.

EXECUTIVE SUMMARY

Environmental Protection Agency (EPA) and Michigan Department of Environmental Quality (MDEQ) regulations require that public water suppliers test drinking water quarterly throughout the distribution system for disinfectant by-products (DBP's). Two categories of DBP's, tri-halomethanes (THM) and halo-acetic acids (HAA5), are regulated and must be tested for. The City of Flint began operation of their water treatment plant (WTP) full time with the Flint River as the source on April 25, 2014. Since that time, four quarters of samples taken have resulted in an annual average violation for total THM. Prior to the first violation (Nov. 2014), the City hired Lockwood, Andrews & Newnam, Inc. (LAN) to complete this Operational Evaluation Report (OER) in conformance with EPA guidelines with the goal to determine the cause(s) of high levels of THM and evaluate possible solutions.

The EPA promulgated the Stage 2 Disinfectants and Disinfection By-Products Rule (DBPR) in January 2006 which set maximum contaminant levels (MCLs) for total trihalomethanes (TTHM) and HAA5 based on an annual running average, tested quarterly, for a given sampling location. The City of Flint reports levels from 8 sampling test locations. Of the four quarterly sampling cycles since Flint began operating the WTP full time, HAA5 levels have been acceptable but TTHM levels were high at 4 sampling sites following the third sampling cycle. Average THM levels exceeded the MCL at 3 sites following the fourth sampling cycle.

A number of issues have been identified as possibly contributing to the high THM levels measured.

1. Inefficient ozone system functionality which has resulted in increased chlorine feed.
2. Upstream source influences in terms of increased chlorine demand.
3. Bypass stream around softening contributed to chlorine demand and increased total organic carbon (TOC) levels in the effluent.
4. Unlined cast iron pipes in the distribution system contributing to chlorine demand.
5. High water age in the distribution system due to:
   a. Broken valves causing less than ideal flow patterns.
   b. Inefficient pump station pressure zones
   c. Water storage volumes in excess of that needed for today's demands.
   d. Oversized water mains
   e. Low water demands
6. High chlorine demand in filters.
7. High THM formation potential (THMFP) in source water.
8. Less than optimal removal of THM precursors

A graphical representation of how the factors above relate to the timing of THM compliance sampling is shown as Table 1. Compliance sampling dates are hatched. Each row in Table 1 describes a factor than can lead to increased THM levels and the table defines when each of those factors applied. Note the convergence of nearly all factors around the second sampling period on August 21, 2014 to create what appears to be a worst case scenario. The table also shows that the factors listed as those that the City can control have been addressed prior to the February sampling period. Monthly operating report data up to February 1,2015 is depicted on the Table.

TABLE 1 - SUMMARY OF NEGATIVE INFLUENCES ON THM COMPLIANCE SAMPLING

FACTOR	2014								2015	
	May	June	July	Aug	Sept	Oct	Nov	Dec	Jan	Feb
Softening bypass stream over 20% of plant flow										
Ozone system not feeding optimally										
Using full water storage capacity of WSR & CSR										
Chlorine feed at WTP 7.0 mg/l or more										
Ferric chloride feed rate less than 10 mg/l Fe3+										
Raw water temp 23 degrees C or more										
Raw water TOC levels above 8.0 mg/l										
Raw water coliform over 5000 counts/day										
Positive bacteria test in dist. system (boil water notice)										
Water demand less than 15 mgd										

Dates of occurrence
Dates of occurrence and expected to repeat in future years
Compliance sampling date

System factors

ACTION PLAN

The City of Flint has signed an agreement with the Karegnondi Water Authority (KWA) to purchase raw water drawn from Lake Huron. The KWA system is currently under construction and expected to be operational by late 2016. The water supply from Lake Huron will have entirely different water quality characteristics from the Flint River and those characteristics are expected to yield drastically reduced DPB formation. With that, non-structural options to help reduce THM levels are much preferred over solutions requiring new construction. Therefore, two categories of actions have been devised: Stage 1 being actions that can be completed relatively quickly without major construction and Stage 2 consisting of either long term actions or solutions requiring major construction. The City is actively working to complete Stage 1 actions as soon as possible. Stage 2 actions are to be implemented only if Stage 1 actions are ineffective in adequately reducing TTHM levels and therefore Stage 2 is contingent upon the outcome of Stage 1. As of the date of this report, status updates for action items are shown in red.

Stage 1 – Immediate Actions

- Hire third party water quality expert to complete independent 'water audit'
  - The City hired Veolia Water to review all water quality related operations, procedures, actions taken and planned responses. Recommendations from Veolia are expected by the first week in March 2015.
- Obtain an in house THM analyzer to allow regular operational monitoring of THM levels
  - THM analyzer was installed 2/17/15.
- Hire ozone system manufacturer to troubleshoot ozone system
  - Manufacturer and controls programmers performed on site evaluations in January 2015. ⟶ Findings ?
- Bench scale jar testing
  - Match existing process and assess possible areas of improvement
    - Existing process was simulated and an evaluation of existing chemical feed dosages has been completed by LAN.
    - Existing process TOC profile was developed by Veolia.
  - Simulate potential modifications to treatment process
    - Soda ash softening evaluation completed and PAC feed testing completed by LAN.
  - Evaluate coagulation and flocculation polymer aid feeds to assist with TOC removal
    - Evaluations of polymer aids completed by LAN and PVS Technologies.
- WTP operational changes
  - Discontinue softening bypass stream to reduce chlorine demand
    - Operational directive has been set to soften no less than 80% of flow.
  - Disinfection of filter beds to reduce chlorine demand
    - Utility Service Group contracted by City and condition assessment completed. Controls improvements have been completed.
  - Begin coagulation and flocculation polymer aid feeds to assist with TOC removal if bench scale test results are positive
    - Jar testing completed to date has not indicated a useful benefit to feeding coagulation/flocculation polymer aids. Increased ferric doses have been implemented at the WTP based on positive jar test results.

Based on [illegible] w. Maximum [illegible]

- Increase water main flushing efforts to minimize stagnant water
  - Flushing efforts are ongoing as weather permits.
- Water system modeling to identify areas with high water age and potential solutions
  - The water model has been improved and preliminary results, including system wide water age, have been produced. Water demand updates and reconciliation with operator's data are scheduled for March 2015 to complete water modeling analysis.
  - Cedar Street Pump Station potential recirculation
    - Water model analysis to be completed in March 2015.
  - West Side Pump Station potential recirculation
    - Water model analysis to be completed in March 2015.
  - Storage tank volume use
    - Operating levels of West Side and Cedar Street reservoirs have been lowered to reduce water age.
  - Possible broken closed valve locations
    - Model has been updated with known broken valve locations. Model results are being evaluated for indications of other possible broken valves. City has also initiated valve assessment program.
  - Locations in need of flushing
    - High water age areas have been identified in the water model. Further evaluation forthcoming to determine most effective flushing points.

Stage 2 – Contingent Actions

- Fix ozone system
  - Repairs have been made to gauges and programming and the system is producing proper ozone and functioning under manual operation. Further minor repairs are planned for the 1st quarter 2015 to allow automatic operation.
- Start feeding coagulation and flocculation polymer aids to lower TOC, if not completed in Stage 1
  - Polymers evaluated by LAN did not demonstrate notable benefit.
  - PVS Technologies evaluated a proprietary polymer that showed little benefit.
- Convert to lime and soda ash softening
  - Cost effective analysis to be developed, if necessary, based on routine operation THM level monitoring.
- Change disinfectant to chloramine or chlorine dioxide until KWA
  - Cost effective analysis to be developed, if necessary, based on routine operation THM level monitoring.
- Install pre-oxidant feed at intake to optimize ozone disinfection
  - Permanganate feed at intake was evaluated by Veolia the week of 2/16/15 and recommendations are expected by the first week in March 2015.
- Replace filter media with granular activated carbon (GAC) media
  - Cost effective analysis to be developed, if necessary, based on routine operation THM level monitoring.
- Implement advanced treatment for THM precursor removal
  - Cost effective analysis to be developed, if necessary, based on routine operation THM level monitoring.
- Increased main flushing based on water modeling results
  - Water model analysis to be completed in March 2015.

- Continue valve replacements with water model assistance
  - Water model analysis to be completed in March 2015.
- Emphasize cast iron pipes on water main replacement priority list
  - Flint has bid replacement of over 2 miles of 24" cast iron pipe along Dupont and Bishop Streets to be completed this coming construction season. The water main section is considered a critical transmission main, and is expected to contribute to decreases in water age when complete

THM samples have been taken and tested 5 times since the City began using the Flint River for supply. Four sets of samples were taken for official regulatory compliance and one set of samples was taken by the City for operational monitoring. Samples were taken in May 2014, August 2014, November 2014, January 2015, and February 2015. THM levels at all sample sites have declined from August 2014 to February 2015. The average of all sample sites in August was 142.1 ug/l and the most recent average of samples taken in February 2015 was 19.8 ug/l. The MCL defined by the EPA is 80 ug/l.

I. BACKGROUND

The City of Detroit Water and Sewer Department (DWSD) has historically provided drinking water for the City of Flint and Genesee County. In the late 1990's growing concern regarding the reliability of the DWSD supply prompted the City of Flint to upgrade their existing water treatment plant (WTP). Those improvements, defined as Phase I, were completed in 2005 and were intended to allow the Flint WTP to operate, using the Flint River as the source, for an extended period of time in the event that supply from the DWSD was temporarily interrupted. Additionally, the Phase I improvements set the stage for Flint to break free from dependence on the DWSD supply and water charges over which they had no control.

A. WATER SUPPLY TRANSITION

1. Detroit Water and Sewer Department (DWSD)

Until recently the Genesee County and Flint region had been provided drinking water by the DWSD. However, due to excessive cost increases and reliability issues with the DWSD system other options had to be explored.

2. Karegnondi Water Authority (KWA)

In 2010 the Karegnondi Water Authority (KWA) was formed for the purpose of developing a new water supply from Lake Huron to serve the region in lieu of the DWSD supply and the City of Flint elected to join. The KWA expects the new system which is currently being constructed to become operational by the fall of 2016.

3. Flint River – Interim Period

With a renewing water supply agreement between Flint and the DWSD being terminated by the DWSD (effective April 30, 2014) and the KWA system not expected to be operational until late 2016, the City of Flint decided to initiate operation of the existing WTP full time utilizing the Flint River as the interim water source. A variety of WTP improvements were necessary for the Flint plant to become a full time plant. For purposes of this report, Phase II improvements to the Flint WTP are improvements intended to allow the plant to operate full time with either the Flint River as the source or the KWA supply as the source.

B. TTHM VIOLATIONS

The EPA and MDEQ method of determining if TTHM sample results exceed the MCL uses a locational running annual average (LRAA). Flint's first TTHM violation was cited by the MDEQ following the third cycle of sampling completed in November 2014. Of the 8 sampling sites, 4 were in violation. At that time the MDEQ used the following calculation for determining if the MCL had been violated:

(2 x current quarter value + previous 2 quarter values) / 4 = Operational Evaluation Value

Flint has now completed tests for 4 quarters and a straight annual running average applies. Based on samples taken on February 17, 2015 the number of sites in violation of the THM MCL limit has decreased to three. The City also conducted a round of sampling on January 27, 2015 in order to internally monitor the progress of actions taken to address the THM issue. It is worth noting that each round of sampling since August of 2014 has indicated a significant drop (improvement) in THM levels. Test results are tabulated in Table 2. HAA5 sample results are shown in Table 3, of which Flint has had no violations.

HAA5 MCL = 60 ug/l

C. WATER TREATMENT PLANT RECENT IMPROVEMENTS & STATUS

1. Phase I WTP Improvements

Since 1965, the Flint WTP has remained a secondary or backup supply system to the DWSD primary supply. Typically the secondary supply for a public water system is expected to be needed only during emergency situations and normally is designed for short term operation such as providing the average daily demand for a few days. Conversely, Phase I improvements were designed with the intent to upgrade the Flint WTP in order to allow for an extended short term period (6 weeks) because of the perceived high risk that the DWSD supply would fail and remain out of service for an

extended duration. Regardless, the Flint WTP was still intended to serve as a standby plant and as such the Phase I improvements lacked redundancies that would be required for a primary supply WTP.

2. Past Pilot Study & Testing

During design of the Phase I improvements a treatability study was completed by Alvord, Burdick & Howson, LLC (AB&H) in 2002. The Treatability Study evaluated the current treatment processes that are in place at the Flint WTP today with the Flint River as the source. The report recommended the following:

TABLE 4 – 2002 WTP TREATMENT RECOMMENDATIONS

Treatment	Purpose	Point of Application	Dosage (mg/l)
Sodium permanganate	Zebra mussel control	Intake	0.3
Ozone	Taste & odor removal, disinfection	Diffusor basin	1.5
Ferric chloride	Coagulation	Rapid mix	40
Coag aid polymer	Turbidity & TOC removal	Rapid mix	2.0
Floc aid polymer	Turbidity & TOC removal	Floc basin	0.05
Lime	Softening	Softening basin	175
Soda ash	Softening	Softening basin	52
Carbon dioxide	pH adjustment	Recarb basin	37
Media filters	Filtration	N/A	Na
Chlorine	Disinfection	Filter effluent	1.0

Of the recommended items, zebra mussel control, coagulant and flocculation polymer aids, and soda ash feed have not been incorporated into the treatment process.

3. Phase II WTP Improvements for Full Time Operation

Phase II WTP improvements are those needed to convert the Flint WTP from a back-up supply to a primary supply plant. A number of improvements have already been constructed as they were necessary to operate full time when treating water from the Flint River. The improvements under the title of Phase II that have been completed or are nearly complete include installation of the future raw water feed connection point and valving for the KWA supply, upgrades to the lime sludge lagoon, the lime sludge lagoon decant and disposal system, decant pump station and force main, installation of mid-point chlorination before filtration, and upgrade of the electric feed sub-station.

Additional improvements to the Flint WTP that are to be completed to become part of the normal treatment process using water supplied by the KWA are:

- New oxygen and nitrogen storage facilities for the ozone system (under construction)
- New coagulant feed system
- Electrical
  - Pump Station #4 upgrades (under construction)
  - SCADA and controls upgrades
  - Filter transfer pump station feeders
- Pump replacements and VFD installation in the low and high service pump station (under construction)
- Filter transfer pump station to Dort Reservoir
- Facility security improvements

II. SOURCE WATER EVALUATION

A. DATA ANALYSIS

Based on past data collected and the 2002 Treatability Study by AB&H, the Flint River water quality varies seasonally with higher hardness and alkalinity experienced in the winter. Higher magnesium concentrations are also experienced in the winter, adding difficulty to the settling process due to neutrally buoyant floc. General water quality average characteristics recorded for the 2002 Treatability Study as compared with average characteristics recorded in 2014 are shown in Table 5 below.

TABLE 5 – FLINT RIVER WATER QUALITY CHARACTERISTICS

Period	Turbidity NTU	TOC Mg/l	Alk. Mg/l	Hardness Mg/l as CaCO3	pH	Total Col. Count/day	THMFP Mg/l
2001 Apr–Oct	7.9	9.4	215	272	8.1	870-1230 (7300 max)	410
2014 May–Oct	8.3	10.3 5/22/14	207	252	8.2	1900-9000 (48,300 max)	187

The Flint River characteristics do not appear to have changed significantly over the past 10+ years. Note that further investigation by City staff revealed a sewer leak upstream of the plant that may have contributed to the total Coliform count. The leak was subsequently repaired.

B. CONCLUSIONS

Considering the minor changes in Flint River water quality, much of the information contained in the 2002 Treatability Study by AB&H remains relevant today. Data from that report assumed to be consistent today include the following:

- Flint River is influenced by groundwater from a dolomitic aquifer
- Hardness varies seasonally with higher hardness and alkalinity in the winter
- Hardness, alkalinity, magnesium concentrations tend to be reduced by run-off

In development of the 2002 Treatability Study, processes were simulated which resulted in low THM levels. Therefore, information contained in that report will be used to assist with establishing a baseline jar testing procedure as discussed further in Section III.

III. TREATMENT PROCESS EVALUATION

A. EXISTING PROCESS DESCRIPTION

The existing WTP consists of an intake with screening from the Flint River, low lift pumping, ozonation, rapid mix, flocculation, settling, softening, recarbonation, filtration, storage and high service pumping. A process diagram is shown as Figure 1.

1. Intake

A 72" diameter pipe draws water from the Flint River through 2 traveling screens to the low lift pump structure. No chemicals are currently fed for Zebra mussel control or pre-oxidation as recommended by the 2002 Treatability Study. Manual removal of zebra mussels is more economical than installation of chemical feed equipment considering the short term need.

2. Ozone

There are 2 ozone generators designed to provide adequate ozone for a WTP flow of up to 36 mgd. There are 3 ozone contact basins. The ozone generators were designed to produce 900 lbs/day at 10% concentration and up to 1300 lbs/day at 6% concentration each. Prior to recent repairs, readings indicated a production rate of approximately 700 lbs/day at 4% concentration. It is possible that before the recent improvements the ozone feed might not have been optimized. In fact, it is known that less than optimal ozonation previously led to increased chlorine feed which would have contributed to THM formation.

3. Rapid Mix

East and West rapid mix chambers allow chemical feed prior to the flocculation basins. Each rapid mix chamber is equipped with a 5 hp mixer.

4. Coagulation / Flocculation

The WTP contains two equally sized flocculation basins, east and west, and each basin provides tapered or gradually slowed mixing from inlet to outlet. There are fifteen 2 hp mixers for each basin with VFDs to control mixing speed. The 2002 Treatability Study recommended feeding both coagulation and flocculation polymer aids. Neither polymer aid is being used today because turbidity and TOC removals have been sufficient to meet regulatory requirements.

5. Settling

Primary clarification takes place within 3 basins containing plate settlers. The settlers are operating as designed.

6. Softening

Again, there are two basins for softening: east and west. Each basin is 120' in diameter and contains a solids contact softening unit. Each softening basin/unit has a design capacity of 18 mgd. The east clarifier has an effluent weir imbalance that the City intends to fix when low demands allow for construction. Low lift pumping limitations, flow control to the basins, control restrictions on residuals removal, and fluctuating demands have made it difficult for WTP staff to stabilize the softening process. Softening is accomplished by feeding lime. The decision was made by the City not to feed soda ash in order to remove non-carbonate hardness because acceptable hardness levels could be achieved with lime feed only and softening is short term until Lake Huron water becomes available. Lime and soda ash softening is a possible consideration to assist with TOC removal and thus reduce THM formation.

7. Recarbonation

Recarbonation for pH adjustment is accomplished in east and west recarbonation basins between and to the north of the softening basins. Carbon dioxide storage and feed equipment is located west of the recarbonation basins.

8. Filtration

Filtration is accomplished with 12 dual media filters, equally sized and designed to filter 3.0 mgd each. Media consists of 12" of sand and 18" of anthracite. The filters have been operated intermittently over the years due to the standby nature of the WTP and until recently, chlorine injection took place downstream of the filters. It is possible some microbial growth had developed in the filters leading to increased chlorine demand. The City recently hired a contractor to upgrade the electrical controls for the filters and that work has been completed.

9. Disinfection

Disinfection is provided by ozonation and by feeding chlorine. Ozonation occurs at the front end of the WTP. Chlorine is fed prior to filtration and prior to finish water storage / high service pumping. The intermediate chlorine injection location was recently constructed under the Phase II, Segment 1 contract.

10. Clear Well & Pumping

The pump building sits adjacent to a 3 MG clear well and contains both low and high service pumps.

B. JAR TESTS / EXPERIMENTS

1. Approach

There are several well practiced methods by which DBPs can be reduced. First, the disinfectant can be changed to an alternate that has a lower tendency to form DBPs. Second, additional treatment systems such as activated carbon or air stripping (depending on the nature of the precursors) can be added to remove DBP precursors. Lastly, the existing treatment processes can be optimized to remove as much DBP precursor as possible. Of these options, optimizing existing treatment processes is the only strategy that does not require the construction of new and expensive facilities. It is anticipated that Flint will be receiving Lake Huron water in approximately two years and this water will have a completely different chemistry from the Flint River. Major process changes instituted to address THM levels using Flint River water are likely to be unnecessary for Lake Huron water and may even be inappropriate. Therefore, those options which require addition of new treatment processes are undesirable at this time. In recognition of this upcoming change in water source, efforts for this study have concentrated on improving the existing processes, rather than adding new ones. New treatment processes will only be recommended if operational changes to the existing treatment train prove ineffective.

Recent sample test results suggest that most of the DBPs are formed in the distribution system rather than within the treatment plant. Therefore, the most logical approach is to reduce the DBP formation potential (DBPFP) rather than simply lowering the levels of DBPs leaving the plant. During bench scale testing, formation potential (FP) levels were the primary indicator of success or failure of proposed process modifications.

2. Protocol

Bench scale pilot testing is intended to reflect actual plant operating and hydraulic conditions so the bench scale treatment units were sized based on various dimensionless factors to ensure the pilot treatment matched the actual system. Bench

scale ozonation was not practical due to time and cost limitations. Therefore, water samples were withdrawn from the plant ozone basin effluent. These samples were transported to the laboratory and dispensed into square testing jars. The jars were used to simulate rapid mix, three-stage flocculation, and settling. Rapid mix and flocculation conditions were matched to the plant based on "Gt" values. The "G" value is a measure of the mixing intensity and is a function of mix time, viscosity of the liquid, and mixing power applied to the water. "Gt" then, is a size scaling factor where time has been accounted for. Settling time was scaled to match the shorter settling depth of the testing jars. After settling, samples were decanted from the test jars. The decanted samples were then lime softened; softening conditions were similarly matched on the basis of "Gt". Carbon dioxide was sparged into the samples to reduce the pH. The water was then vacuum filtered through filter paper, sized to simulate the plant's dual media filters. The samples were dosed with excess chlorine and allowed to react for seven days at 25° C before testing for DBPs to determine the formation potential.

The following conditions were applied during testing to properly match small scale testing to actual plant processes.

TABLE 6 – BENCH SCALE TEST MIXING INTENSITIES

Process	G	Duration	Mix RPM
Ozonation	Plant	-	-
Rapid Mix	200	44 sec	160
Flocculation, Stage 1	50	9 min	55
Flocculation, Stage 1	25	9 min	30
Flocculation, Stage 1	12	9 min	19
Settling	N/A	10 min	-
Softening	TBD	10 min	-
Recarbonation	N/A	N/A	-

The primary variables during testing were chemical additions and chemical dosages. Specific chemicals and dosages used for initial testing conditions were selected to reflect current plant usage and the recommendations of the 2002 Treatability Study:

TABLE 7 – BENCH SCALE TEST CHEMICAL FEED RATES

Chemical	Current Usage	2002 Study	Test Values
Ozonation	4.66 mg/l	1.5 mg/l	
Ferric Chloride	7.7 mg/l Fe3+	40 mg/l Fe3+	7.7 – 80 mg/l Fe3+
Coagulant Aid Polymer	Not used	2.0 mg/l	1 – 2 mg/l
Flocculation Aid Polymer	Not used	0.05 mg/l	0 – 0.05 mg/l
Powdered Acuvated Carbon	Not used	N/A	20 – 100 mg/l
Lime	120 mg/l	175 mg/l	120 – 175 mg/l
Soda Ash	Not used	52 mg/l	0 – 52 mg/l
Cationic Softening Polymer	3.13 mg/l	Not used	3.13 mg/l
Anionic Softening Polymer	0.88 mg/l	Not used	0.88 mg/l
Fluoride	0.45 mg/l	1 mg/l	Not used
Carbon Dioxide	32 mg/l	37 mg/l	Fed to reach pH of 7.5 +- 0.3
Chlorine	6.3 mg/l	3 mg/l	10 mg/l

3. Considerations

The 2002 Treatability Study did not note significant formation of DBPs. This may be a function of different Flint River water chemistry at that time. However, recognizing the considerable differences in chemical usage and dosages between that study and current operations, those differences in chemical use and dosage are an obvious starting point for optimizing treatment to prevent DBP limit exceedance.

Although it is believed that optimization of current treatment can correct the DBP issue, should optimization of present treatment prove insufficient, alternate residual disinfectants (chloramines and chlorine dioxide) will be investigated as additional treatment measures.

4. LAN Test Results

Two rounds of jar testing were completed by LAN during the weeks of December 15, 2014 and January 26, 2015.Detailed test data is included in Appendix A. Testing results can be summarized as follows:

- Increased dosages of ferric chloride resulted in higher reduction of THMFP.
- The currently utilized feed rate of lime at 120 mg/l is appropriate
- Softening with soda ash in addition to lime resulted in minor additional THMFP reduction – in the range of 0% - 10%.
- The benefits of using a cationic polymer during softening at a dosage range of 0.31 - 3.13 mg/l to help reduce THM's are unclear
- The benefits of using an anionic polymer during softening at a dosage range of 0.09 – 0.88 mg/l to help reduce THM's are unclear
- Feeding PAC was ineffective in reducing THMFP within the dosage range of 20 – 100 mg/l.

5. Testing by Others

In addition to jar testing completed by LAN, the chemical supplier who provides ferric chloride for the City, PVS Technologies, ran tests using their recommended flocculant polymer aid. Plus, Veolia Water completed jars testing of their own the week of February 16th to analyze other process details and current WTP parameters. Experiments completed by PVS Technologies showed very little TOC removal beyond that obtained with straight ferric chloride feed.

6. Conclusions

Increasing the dose rate of ferric chloride is an operational change that can easily be implemented without the need for any additional equipment. Test results show that over 40% THMFP removal can be obtained with a dosage of 60 mg/l Fe3+ or higher. Increased dosing of ferric chloride would be most ideal coupled with regular raw water TOC monitoring so that TOC levels would dictate the appropriate ferric chloride feed rate.

Softening with soda ash in addition to lime is another option the City should consider if increased ferric chloride doses are not adequate to maintain THM levels under the MCL, particularly during warmer months. Again, monitoring of TOC in the raw water could provide useful information of when lime/soda ash softening is necessary.

IV. DISTRIBUTION SYSTEM EVALUATION

EPA guidance for the distribution evaluation portion of an OER is focused on identification and isolation of a specific portion of the distribution system that led to the exceedance. The circumstances of Flint's apparent pending TTHM exceedances are unusual in that a new supply has been implemented which clearly corresponds to the high TTHM sample results. Although the new source is one element in increased TTHM levels, value remains in evaluating the distribution system since water age is also a critical factor. Additionally, there may be distribution improvements that can be made to help alleviate the problem.

A. INFRASTRUCTURE

1. Piping

According to the most recent MDEQ Sanitary Survey, the distribution system is estimated to contain 70% cast iron, 20% ductile iron, 2% concrete and 8% steel water mains. Unlined cast iron pipe can become pitted, allowing colonization sites for microorganisms leading to chlorine demand. Additionally, much of the piping in the system is aged and in poor condition. Increased chlorine demand could be resulting from biofilm in older pipes and from main breaks/repairs. The extent of contribution is not known but any water main replacement project will decrease chlorine demand somewhat if constructed properly. Unfortunately, water main breaks may also assist with decreasing water age by providing unintentional flushing. All things considered, it is impossible to quantify the impact existing piping has on THM formation.

The City utilizes City Point software and GPS equipment to document main breaks and prioritize replacements. However, main break information is more pertinent to rusty water complaints and has little relevance to THM levels. Areas that have been targeted for main replacements include the transmission main from the WTP west to Dupont and south to the West Side reservoir, Fenton Road, Atherton Road, Dort Highway, Averil Street, and Boulevard Drive.

2. Storage

There are 4 finish water storage tanks and 1 raw water tank as tabulated below:

TABLE 8 – STORAGE TANKS

Name	Type	Water	Volume (MG)	Operating		Absolute	
				LWL	HWL	Bottom	OF
Dort Reservoir	Ground	Raw	20	-	-	730	750
WTP Tank	Elevated	Finished	2	883.0	896.0	863.0	898.0
WTP Clear Well – PS #4	Ground	Finished	3	11'	15'	708.5	726.0
Cedar Street Reservoir	Ground	Finished	20	-	11'	737.2	757.2
Westside Reservoir	Ground	Finished	12	-	12'	761.8	779.0

The MDEQ typically recommends providing a minimum finish water storage volume of 1/3 the maximum daily demand (MDD). According to the 2013 MDEQ Sanitary Survey, the 5 and 10 year MDDs are 21.57 mgd and 30.05 mgd respectively. A common rule of thumb for clear well storage volume at a WTP is 10% of the design flow rate. Another general guideline for reliability is to provide total storage to allow for 2 X the average daily demand plus fire flow demand. For this analysis, fire flow is assumed to be 2,500 gpm for either one industrial fire (2,500 gpm) or a combination of one residential (1,000 gpm) and one commercial (1,500 gpm) fire at a 4 hour duration which results in a total volume of 600,000 gallons. These go-by

approximations are summarized below with the applicable flow rates and are compared to the existing storage volumes currently being utilized.

Common Practice	Flow Rate	Recommended Volume by ROT	Volume In Use
Clear well 10% of Design Flow	18 MGD	1.8 MG	3.0 MG
Finish Storage = 1/3 MDD	30.05 MGD	10.0 MG	37 MG
Total Storage = 2 * ADD + FFD	13.87 MGD	28.3 MG	57 MG

Based on the values above, it appears the storage volume used in the Flint system could be decreased without negatively effecting reliability. The appropriate volumes of individual tanks will be further evaluated using the water system model and discussed in Section V (C).

All reservoirs have baffling to minimize stagnant water. Also, all tanks have been maintained and are in reasonable condition. The Westside reservoir has an exposed roof that is in need of rehabilitation, but its current condition has no influence on THM formation.

3. Pump Stations

All pump stations are in good condition but pumps are generally oversized. As an independent consideration, oversized pumps are not a contributing factor to high THM levels. Control of pumps and pressure zones are discussed in detail below.

B. OPERATIONS AND MAINTENANCE

1. Pump Station & Storage Operations

Pump stations and storage tank levels are controlled as shown in Table 9.

TABLE 9 – PUMP STATION CONTROLS

PS Name	Control Point	On Point	Off Point
PS No. 4 Raw	Operator	-	-
PS No. 4 Finish	Match plant flow	-	-
Westside	System pressure (elevated tank)	22.5'	33'
Cedar Street	System pressure (elevated tank)	22.5'	33'
Torrey Road	Distr. – Brown/Bradley	< 45 psi	≥ 45 psi

Cedar Street and Westside pump stations are operated as needed and they are alternated. Typically, Cedar Street is run in the morning and Westside is run in the evening and reservoirs for each are filled during low demand periods at night.

Westside, Cedar Street and Torrey Road pump stations are used to boost system pressure when high demands warrant it, but there are not well defined pressure zones within the system. Therefore, the possibility exists that water is being recirculated allowing for increased water age.

2. Booster Disinfection Practices

Booster disinfection is provided at the Cedar Street and Westside pump stations. When sustained residuals are not provided by chlorine feed at the WTP, sodium hypochlorite is applied at the reservoirs while being filled.

3. Changes in System Demands

Water demands in the City have been declining since the 1960's as the population has dropped. As a result, many of the water system components are oversized including storage tanks and water mains which both increase the time for water to reach the user.

From a short term perspective, Flint demands tend to increase in summer as is ordinarily expected but also in the winter due to water main breaks. The MDD for Flint often occurs in winter. Regarding THM formation, with lower temperatures and higher flows in the winter, THM levels taken at the distribution sample points are expected to be lower than at other times of the year.

C. WATER SYSTEM HYDRAULIC MODELING

As part of this report, the City provided a hydraulic water model, originally developed by Potter Consulting, for LAN to update. Thus far, LAN has modified the model to be capable of extended period simulations, modified controls to reflect current operations, revised the piping to include known broken valve locations, and developed preliminary water age results throughout the entire system. Water age shown in the updated model corresponds well to TTHM levels at 6 of the 8 sampling sites. However, LAN has also identified several deficiencies within the model that require further adjustments to allow for usable and reliable results. Those model deficiencies include outdated demands, improperly located appurtenances, and incorrect flow patterns. Preliminary water age results are presented in Table 10. Revised results will be provided when the hydraulic model has been fully updated.

Fine tuning model

TABLE 10 – PRELIMINARY WATER AGE FROM WATER MODEL

Sample Point	Location	Address	Water Age (Hrs)	Aug 2014 THM (ug/l)
1	McDonalds	3719 Davison	23	145
2	BP Gas Station	822 S. Dort Hwy	18	112
3	Liquor Palace	3302 S. Dort Hwy	15	127
4	Taco Bell	3606 Corunna	128	181
5	Univ. Market	2501 Flushing	178	196
6	Salem Housing	3216 MLK	58	112
7	Rite Aid	5018 Clio	78	144
8	N. Flint Auto	6204 N. Saginaw	71	118

It is anticipated that topics shown below in italicized font will be detailed after the model is updated in March 2015.

1. Simulation of Existing System

Match existing conditions. Chlorine and THM data may be used to verify model results. We have chlorine feed data at plant and residuals at 10 locations in each MOR, May 2014 – January 2015.

2. Identification of Water System Deficiencies

Specific issues to look at:

- *Worst case at minimum daily demands*
- *Water age in entire system*
- *Recirculating water through pump stations*
- *Use of storage tanks – volumes in particular*
- *Indications of broken valves*
- *Effectiveness of booster disinfection*

Study of worst case hour min MDD vs. 16?

V. RECOMMENDATIONS TO MINIMIZE FUTURE OEL EXCEEDANCES

A. SOURCE

The City of Flint has already committed to the change from the Flint River as the water source to Lake Huron under the KWA system, planned for late 2016. The risk of future TTHM limit violations will decline substantially with the use of water from Lake Huron due to much lower DBP precursors. It is important to recognize that the Flint River will become strictly an emergency supply when the KWA supply becomes available and any investments toward the Flint River should be contemplated accordingly. Recommendations discussed below in this section apply to the Flint River as the source.

Reverting to supply from the DWSD until the KWA supply is available as an option. However, based on information provided by the City of Flint, the annual cost to receive water from the DWSD would be at least $16,000,000/year or $1,333,000/month. Therefore, utilizing the DWSD for interim supply is cost prohibitive under the terms defined by the DWSD.

1. Watershed Management

A volunteer group entitled the Watershed Coalition performs various tasks related to managing the Flint River watershed such as spring cleanups and annual benthic studies to evaluate the river 'health'. No additional action is recommended at this time.

2. Monitoring

The City documents daily raw water flow, pH, alkalinity, carbonate and non-carbonate hardness, chloride, temperature, turbidity and coliform count as part of standard preparation of Monthly Operating Reports (MOR). It is recommended to add raw water TOC and plant tap THM values to daily documented measurements which would provide staff the data needed to establish correlations to predict distribution system THM formation.

3. Intake Operations

The 2002 Treatability Study recommended pre-oxidation in the form of sodium permanganate as a feed at the intake. It is possible the addition of a pre-oxidant such as hydrogen peroxide or some type of permanganate could enhance the ozone process. Veolia evaluated permanganate demand during jar testing the week of February 16th, 2014 and further recommendations will be incorporated when results become available.

4. Seasonal Strategies

Past data indicates the Flint River is influenced by groundwater and in particular, dolomitic spring water. The result is hard water with high concentrations of magnesium and sulfate. Also, hardness and alkalinity are higher during the winter. Upon initiation of supply from the Flint River, the City made the decision to soften with just lime to focus on removal of carbonate hardness. One potential modification that could assist with TOC removal and thus decrease THMFP would be lime and soda ash softening. A temporary caustic soda feed system is recommended to be put in place in case the need for optimized softening arises.

5. Upstream Contamination Issues

Upstream contamination issues are extremely difficult to prevent and even if detected are difficult to locate. Evaluation of raw water data collected for MORs is the easiest

manner in which to detect upstream contamination issues because the data is already collected for treatment purposes. In fact, high total Coliform readings signaled a potential issue recently that the City identified and removed.

An upstream monitoring and warning system could be established to attempt to detect water quality issues or spill event type contamination early enough to adjust treatment procedures or cease intake prior to the contamination reaching the WTP. However, given the imminent conversion to the KWA supply, the period of full time use would likely be far too short to achieve payback on the capital expenditures.

B. TREATMENT PROCESS

1. Operational Recommendations

- Increase ferric chloride dosage: Previous testing in the 2002 Treatability Study, jar testing completed by LAN, and a review of 2014 ferric chloride dosages compared to THM levels leaving the WTP support that increasing the ferric chloride dosage would help reduce THM formation.
- Increased monitoring: Currently, the MDEQ does not require daily reporting of raw water TOC or finished water TTHM levels. However, daily tracking of such levels would allow the City to develop a correlation between the two, thus providing a predictive tool to help manage TTHM levels.
- Coagulation and flocculation polymer aids: The 2002 Treatability Study suggested the use of coagulation and flocculation polymer aids. These polymer aids were shown in the 2002 Treatability Study to increase TOC removal and thereby reduce THMFP. Further evaluation will be completed during jar testing.
- Discontinue softening bypass: The City was previously bypassing a portion of flow around the softening basins because hardness levels did not warrant softening of the full stream. However, this practice was discontinued because it was believed the bypass stream was contributing to chlorine demand and preliminary data has supported that belief. Chlorine demand dropped 0.5 – 1.0 mg/l following elimination of the bypass stream in early November 2014.
- Soften with lime and soda ash: Research has shown that enhanced softening with both lime and soda ash may provide additional TOC removal. The efficacy of this option will be evaluated during jar testing.
- Disinfection of filter beds: In case there has been microbial growth it is recommended the filters be 'shock' treated with chlorine and rinsed. A chlorine injection point was added upstream of the filters during the first segment of Phase II so future growth in the filters should not be an issue.
- Optimization of all existing treatment processes: Depending on bench scale testing conditions and results, slight modifications to all treatment processes might in order to replicate lower DPBFP.
- Discontinue or adjust softening anionic polymer feed: Some anionic polymers have been found to increase TOC. Veolia evaluated the anionic polymer currently being fed during their jar testing and depending on the results, when available, the softening anionic polymer feed should be adjusted accordingly.

2. Infrastructure Change Recommendations

- Fix and/or replace faulty ozone equipment: Since the ozone equipment was installed it has not been used extensively so the hope is that major components remain in good condition and the system can be easily modified to restore proper functionality. The City has scheduled the equipment manufacturer to field inspect the system on December 15, 2014.
- Replace filter media with GAC media: GAC media could help reduce THM levels by reducing both TOC and chlorine demand. For this consideration, the recommended approach would be to first complete small scale testing to verify efficacy. Upon positive results, the next step would be replacement of media in a fraction of the filters following by sampling to measure water quality. Those results would determine the need to replace media in additional filters.
- Change disinfectant to chloramine or chlorine dioxide: If other options prove to be ineffective, conversion to another disinfectant should be fully evaluated. Various characteristics of chloramination indicate an advantage over chlorine dioxide, but a full analysis would provide clarity as to which would be preferred.
- Install pre-oxidant chemical feed: Hydrogen peroxide or a form of permanganate as a pre-oxidant can enhance the activity of the ozone. Chemical feed could be installed at the intake structure or low service pump station, depending on the reaction time required. Use of a pre-oxidant at the intake might also provide the additional benefit of disinfection credit for ozonation with the MDEQ if an ozone residual can be obtained at the ozone process effluent as a result.
- Repair upstream sewer leak: a sewer leak upstream of the WTP intake was discovered and has already been repaired by the City.

C. DISTRIBUTION SYSTEM

Potential distribution issues related to water quality issues discussed in Section IV included old cast iron pipe, oversized infrastructure, and remote storage/pump station locations and operations that might be less than ideal. Recommendations to address those issues are offered in this section.

1. Manage Water Age

a) Storage Tanks

Considering the excess storage capacity discussed in Section IV, in the short term it is recommended that operational changes be implemented immediately to reduce the overall volume of water stored to decrease water age. Immediate operational recommendations include lowering high water levels of reservoirs other than the elevated tank, to reduce the total system wide usable storage volume to 30-36 MG.

In the long term, LAN recommends development of the most ideal options for water model evaluation. Excess storage volume and tank locations within the water system afford Flint numerous options to reduce the amount of storage volume utilized. As a starting point, two recommendations are presented below.

Option 1
- Take West Side reservoir and pump station out of service
- Cut storage volume used in half at Cedar Street reservoir
- Reduce the utilized storage volume of the WTP clearwell from 3 MG to 2 MG
- Adjusted system wide storage volume would be 34 MG

Option 2
- Take Cedar Street reservoir and pump station out of service
- Reduce the utilized storage volume of the WTP clearwell from 3 MG to 2 MG
- Adjusted system wide storage volume would be 36 MG

b) Residence Time in Pipes

Completely redesigning and replacing the water system to match today's demands is not feasible financially and would be a waste of infrastructure with remaining useful life. Going forward, it is recommended that any future main replacement projects be evaluated for possible downsizing. When the water model is fully updated, it will provide a valuable tool in determining which mains can be downsized and to what extent. Replacement of broken valves and valve exercising are also recommended, which are programs that have already been implemented into Flint's regular operations.

Operationally, hydrant flushing is recommended as needed to minimize water age in low flow areas. Again, the updated water model should be used to locate high water age areas and optimal flushing points.

2. Reduce Disinfectant Demand

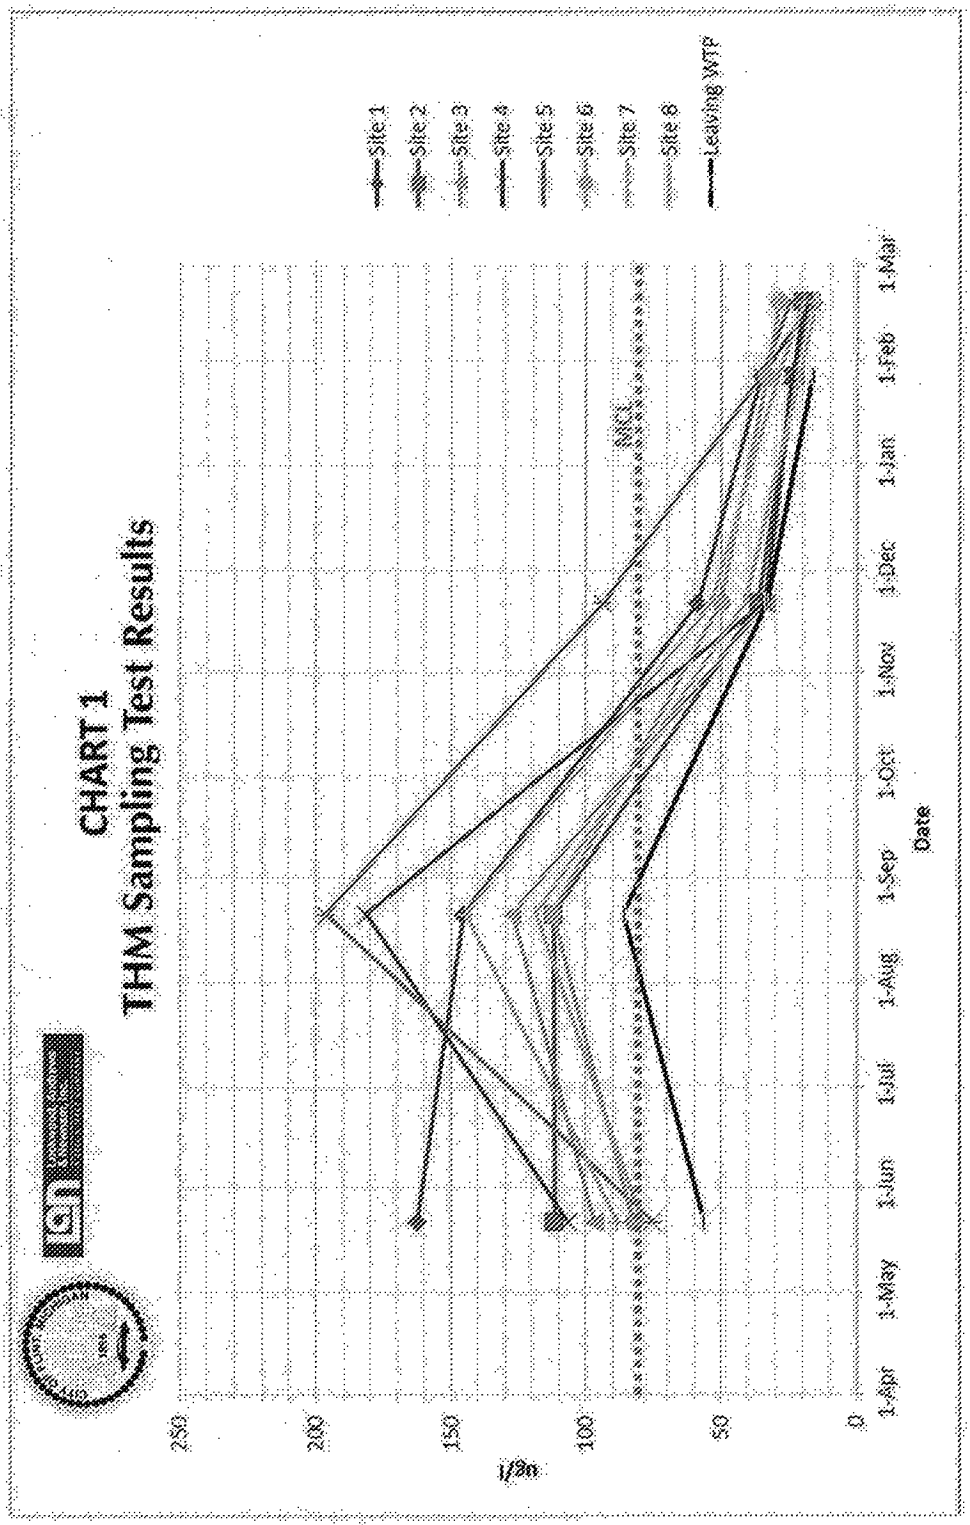
Recommendations to reduce disinfectant demand are similar to those described above to reduce water age. Replacement of old cast iron pipes would lead to a reduction of disinfectant demand on the distribution side, but realistically can only be accomplished over a prolonged period of time. In the meantime, hydrant flushing is the most viable means of reducing disinfectant demand in piping. From a storage standpoint, all reservoirs and tanks should be regularly inspected and maintained to prevent entrance of any outside contamination that would contribute to disinfectant demand.

3. Water Modeling of Recommendations (yet to be completed)

Determine best flushing locations to reduce water age
Evaluate changes in storage tank operations to reduce water age
Valves to close/add to improve pressure zones, reduce recirculation
Optimization of pump station use – smaller pumps? Shut down?
Evaluate booster disinfection

D. BOOSTER DISINFECTION

Decreasing chlorine feed at the WTP and adding booster disinfection in the distribution system is an alternative intended to reduce the reaction time at higher concentrations of chlorine to reduce DPB formation. Extensive looping and branching within the existing system complicate how to best implement and utilize booster disinfection. Water system modeling is recommended to gage the effectiveness of existing feed point locations and dosages. Further discussion and details will be provided when the distribution evaluation results are available.



E. CATEGORIZATION OF ACTIONS

Considering that the Flint River is being used as the water source only until the KWA supply is available (expected late 2016), options to address high THM formation that require new construction or extensive time to implement are not preferred. On the other hand, the City understands THM sample results to date dictate that some action is necessary. Two categories have been developed to assist the City in prioritizing actions to take. Stage 1 consists of actions that can be completed relatively quickly without major construction and Stage 2 actions are either long term actions or solutions requiring major construction. Stage 1 actions are to be completed first followed by evaluation of the results prior to consideration of Stage 2 actions. Grouping of actions are shown in the table below.

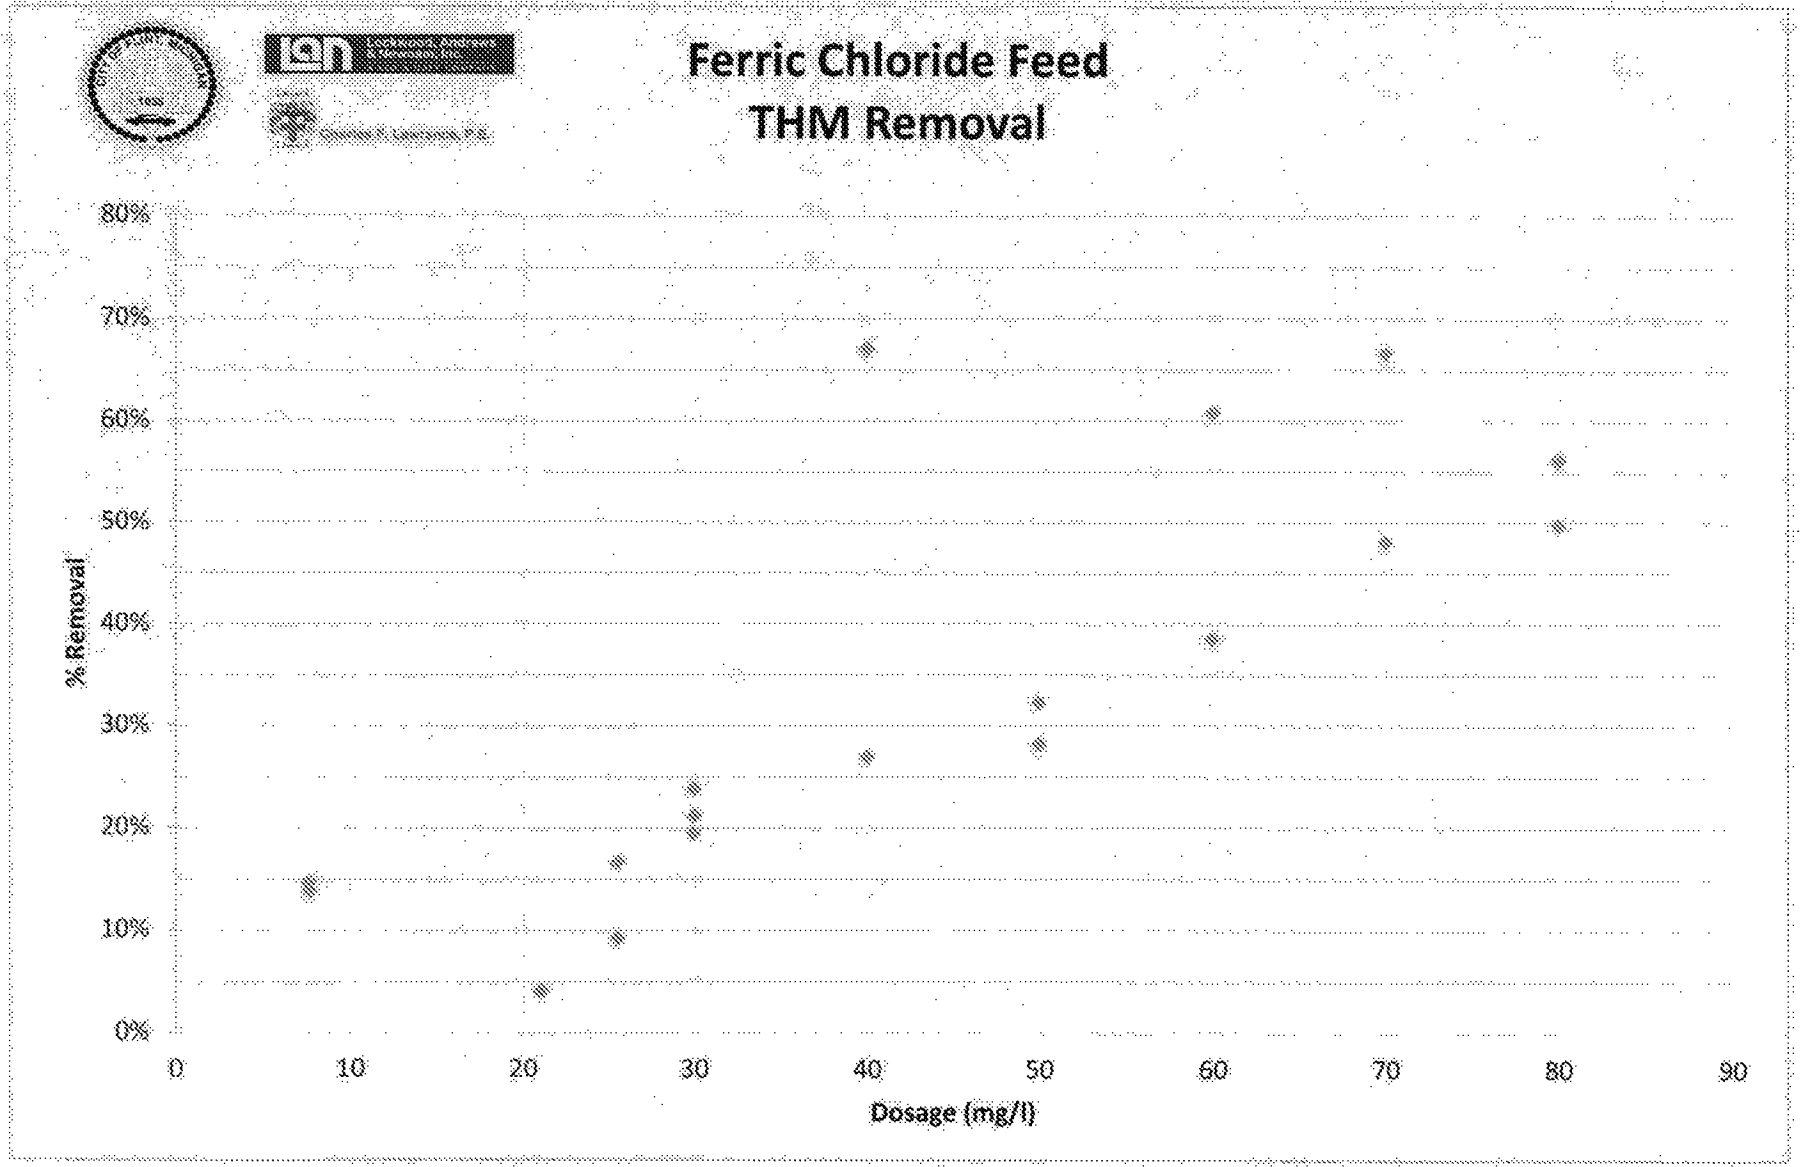


TABLE 11 – ACTION PLAN

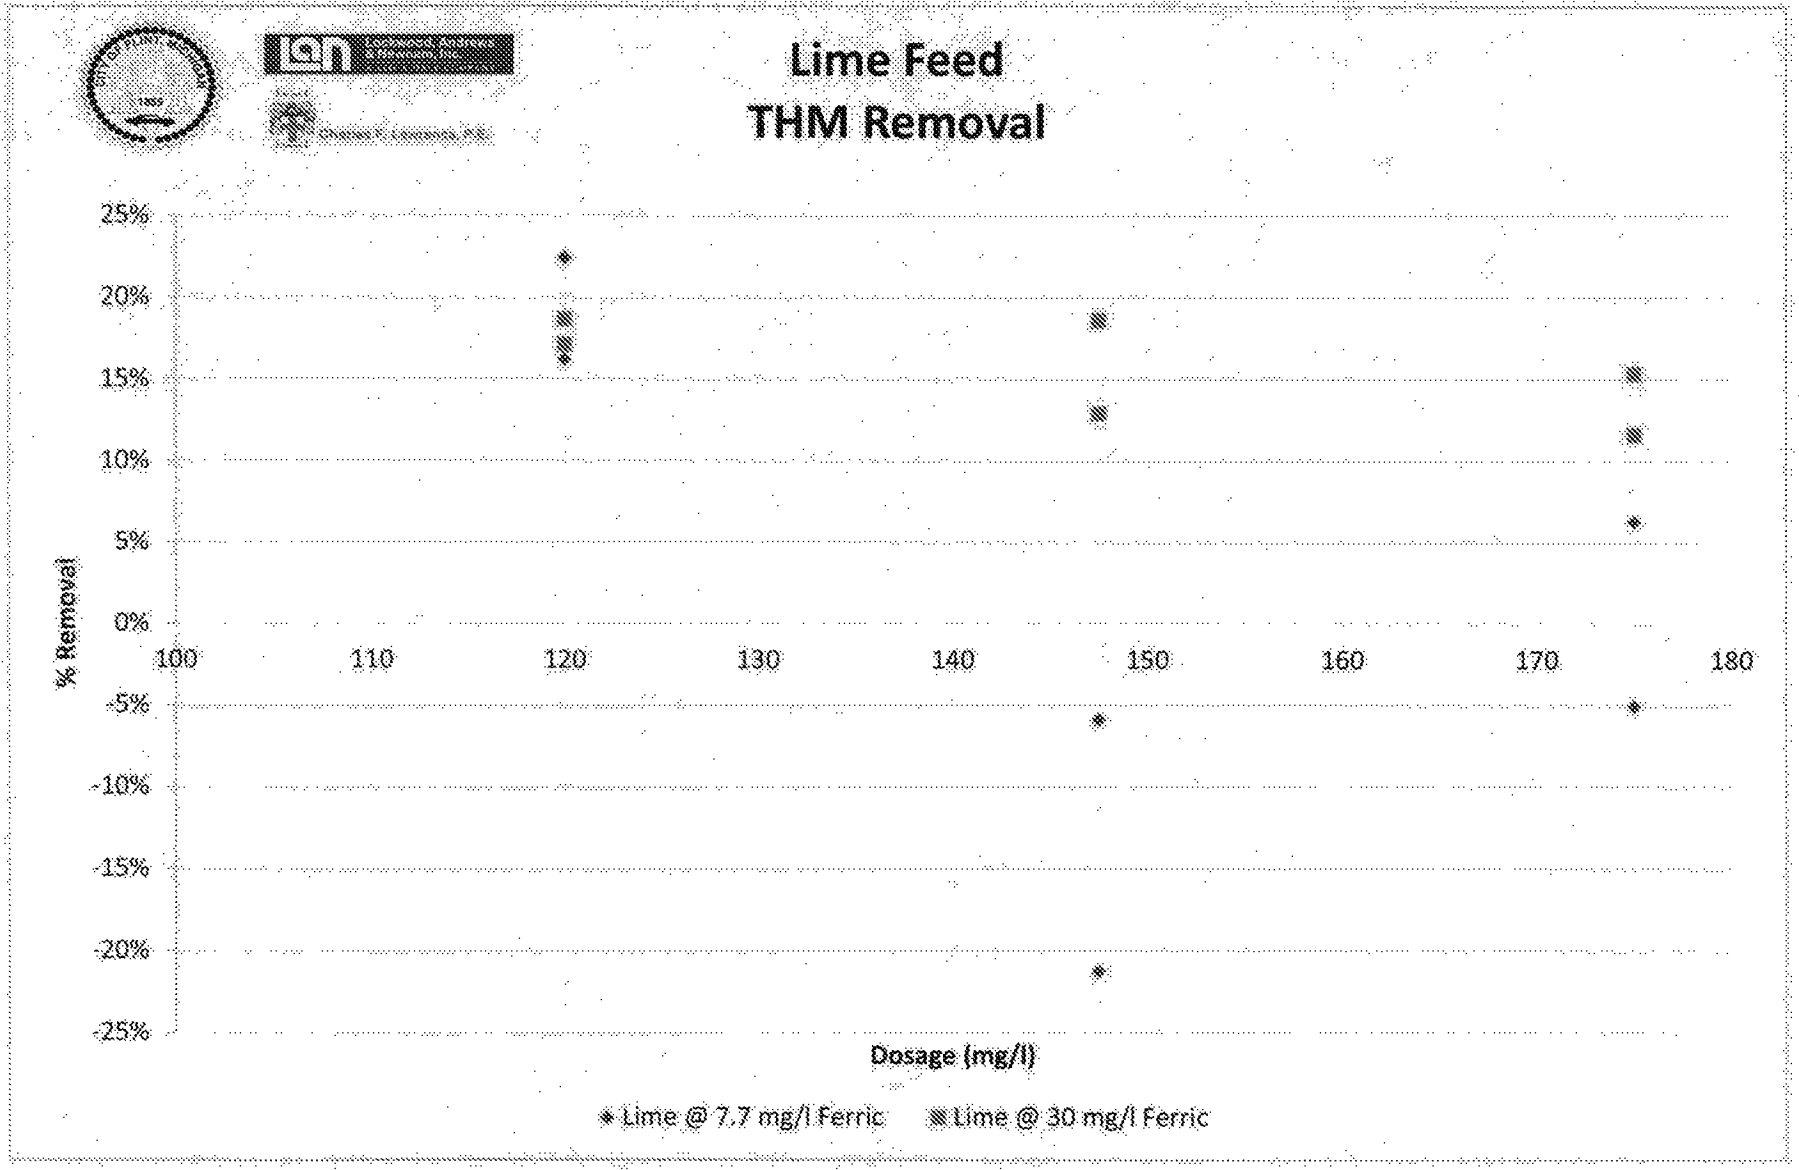
	Action	Purpose
Stage 1	Hire water consultant to complete 'water audit'	Third party review of actions and operations to make sure no options are being missed
	Increased water quality monitoring – obtain THM and TOC analyzers	Provide information needed to adjust WTP operations to match changing raw water quality
	Troubleshoot ozone feed system	Reduce chlorine feed and increase TOC removal
	Bench scale jar testing	Optimize treatment process and evaluate possible modifications
	Discontinue softening bypass	Reduce chlorine demand
	Disinfect filters	Reduce chlorine demand
	Increased water main flushing	Reduce water age / stagnant water
	Water system modeling evaluation	Determine areas with high water age and reasons
	Implement coag. & floc. polymer aids, if appropriate	Increase TOC removal
	Modify booster disinfection feeds, if appropriate	Decrease water age
Stage 2	Repair ozone system	Reduce chlorine feed and increase TOC removal
	Continue increased water main flushing	Reduce water age / stagnant water
	Convert to lime and soda ash softening	Increase TOC removal
	Continue valve replacements based on water model	Reduce water age / stagnant water
	Replace filter media with GAC	Reduce TOC and chlorine demand
	Change disinfectant to chlorine dioxide	Reduce THMFP
	Install pre-oxidant feed at intake	Optimize ozone disinfection, reduce chlorine
	Place priority on replacing cast iron water mains	Reduce chlorine demand



Samples were taken the week of February 16th for the 4th round of quarterly testing. The City has implemented many of the Stage 1 actions and THM test results have significantly improved (decreased) each time samples have been taken since August 2014. In addition to the regular compliance monitoring, the City performed a round of sampling on January 27, 2015. All sampling results are shown on Chart 1.

All,

I am sending everyone the TAC team agenda for Wednesday's meeting, there is room left for general conversation regarding next steps and future agenda's. We look forward to seeing everyone that can make it to City Hall tomorrow.

Thank you,

--

Flint Water
Technical Advisory Committee
May 20, 2015
Flint City Hall

Agenda

2:00 pm	**Welcome** **Purpose of the Technical Advisory Committee: Provide a respectful means of sharing factual information and having dialogue around the City of Flint water.**
2:05 pm	**Introductions**
2:10pm	**Current water status information – M. Glasgow, Operator In Charge (F-1)**
2:20 pm	**Improvements Information – H. Croft, Director Department of Public Works** New filter media installation Leak detection New pipe installation Water meter installation New water page on City website
2:40 pm	**Discussion on next TTHM testing expectations**
2:50pm	**Discussion on current health concerns, including lead and copper testing**
3:30pm	**Next Steps** Next meeting, one month or two months?
3:35 pm	**Adjourn**

Agenda

WTP Status Update

Gibson

- Hardnose 160 - 180 Some last fall
- River Hardnose 250 - 300
- Tox - Sawyer 5 - 10 RAM - Jerk Spring
- 2 - 3 PTAP

Okeechobee Tox weekly - 65% Rom
TTHM → 2 - 35 Loving WTP

Sanford

SAC

Calgon - Stopped installation June
Orange - 4 of the 8 done by Mid-July
or 4 - 6 wks prior to Aug sampling

Six sta locations - Clean / in GAC max
not to be used

MOEQ

11 tracks w MOEQ Rogers & Lu Contractor

Beyond GAC - WTP → Cox / Lu 36 days
Tanks in place / piping
* Lu-Colored support - baby to connect
* Send Sand/GAC to Calgon for column tests
Y/N testing on GAC → Longevity
Lab Selection - RFQ in place
4 week Assessment on River Front Main
Update to Mobile on June 10/14 weeks
Hyd model continues to evolve

24 Transmeon - bids higher than expected
Phase one - challenge
Water meter - long leads
16000 new meters next 2 years
- Outsite - water page UAT/QA
timeline
Review IT & give Hawell feedback
CCR Dec - talk the steps - Multiple meter
Located IN Petaed for local testing
MCC valves - TC, EC capability
Connectivity of public mobile & Secal media
£400,000 to make funded
H Croft - updated us RS Dec 2013 - WAM to see
- 5 YR CIP
Next meeting? - After GNC installed
Late July / E Aug
After E Aug begin looking @ new
FCa use / new egs

Last Meeting 3/31/15

3/31/15 WTP meeting notes

— attempt to make straight run

— stick along to interlock w. min leakage

(1) — Longevity of steel alley? Interim — fill as ok w/ concrete + len cap & seal
> solids work NEXT PLAN

(2) — if not ready to be handled away, then create berm

— use cachet

— excavate 1 time * pile (temp) on north end — take to landfill on ag-use

Phy sep: address city to remove both ponds
— cap in place / remove → will need to dispose (Dawn Rikerby) what makes it "in-cat"

interface w. DPW

Capacity on Lagoon ≥ 3-4 months without discharge of supernatant to San Sewer

2 plant applications to be here (submitted) for WTP / Bray Rd

ok working to
Start Solid waste Sampling by July 1
— due timeline for report (Acol) Oct 1st

UNTP OP

1- Δ source – mgn. Δs due to Δ source
+ op Monitoring

2. OP. oversight – 3 shifts planned

3 Project Schedule
Pump – data inst-QC
mid Nt – ready @ start-up
electrical – ready @ start-up
O2/NOx – storage ⟶ monitoring system to check on chem delivery & turn around time for delivery
plan sent ↑

Goal: start on 9/17

Start-up Goals – Goal to soft start
start-y on 9/17 or
as soon after as possible

* MFI to re-bid @ Re-submittals & input
any further clarifications – work to
* Sure CP & Add Bony Rd addendum to CP

No dates for Report &.

When WTP is ready to roll

Get final sets of plans to
CS for Review

→ set letter drafted

- A.R to do rate Mon. schedule
  or charts — strategy to use in Nov-Feb
  →
- Compl. of Permit for Op. det. I.
- Continue
  Budget (w. own) →
  - Acct work agreement
  - Fact units to
    - Draw water w. Penalty as non-compliance
    - Split Pro Capital
    - Gen. Co. Fac. US — In energy
    - Gen. Co. for Penalty → Final Pay. Gen Co.

Call to Gen Co.

Study Needs Continue

Subject: Flint Water Reliability Study

Mike,

I just remembered that you left me a message a week ago. I'm sorry for not getting back in touch with you earlier. I'll try to answer your questions by this email.

<u>24-inch Water Main / Cedar Street / Torrey Road</u>
Even though the City backed away from the DWRF project this summer, they asked that we still get the projects completed and submitted to the MDEQ for permits just in case they decide to move forward with all or a portion of them on their own . The drawings that were submitted to you are the same projects that were previously in the DWRF package. I don't remember ever submitting final documents for the MDEQ to review and permit. If I am wrong, please let me know.

<u>Water Reliability Study</u>
I also thought that you referenced something about the Water Reliability Study in your voice mail to me. We (ROWE) completed both a Phase 1 and a Phase 2 component of this study. I believe that both the Phase 1 and Phase 2 studies had been previously submitted to you (MDEQ) for review and comment. When you referenced coming over and meeting with the City to review the Phase 2 were you just wanting an update on where they are with starting to work on the improvements that were identified? Please confirm.

If there is something else, please email or call my cell at 810-869-5398. Thanks

Jeff S. Markstrom, P.E., Project Manager

3/19/14
Consultant's Resp. to DEQ's comments on WTP upgrade

Flint WTP Improvements – Phase II, Segments I, II and III

Responses to MDEQ Review Comments dated 3/19/2014

Segment I – Initial Watermain Cut-in

1. Detail 2, Sheet C-504, "Air Release & Access Manhole," shows a 2" corp stop for air release. These are intended to be manual air release valves for exhausting air upon initial filling of the pipeline or after maintenance has been performed and refilling the pipeline. The manhole structure will be checked periodically and pumped out with a portable sump pump as part of the normal plant maintenance program.

Segment 1 – Rehabilitation

1. Raw Water Piping
   a. Maintain back up supply from Genesee County during interim operation at C.S. #2. Installation of the 42" raw water piping has been delayed until the KWA project is closer to being ready to supply water to the City. This will allow the City to maintain the backup supply from Genesee County during interim operation.
   b. The crossing of the new 42" steel pipe over the existing 54" concrete pipe is shown in plan on drawing sheet C5-101, with Detail 5, Sheet C5-501 showing how the 42-inch line will be supported. As shown on Detail 5, Sheet C5-501, the new 42-inch line will have concrete pipe cradles constructed on either side of the existing 54" pipe, maintaining a minimum clearance of 12" on either side of the 54" pipe. Pipe loads from the 42" line will then be transferred to the pipe cradles and into the soil, and not the 54" pipe. The 6" clearance between the two pipes will be backfilled with CLSM material as it will be impossible to compact typical granular bedding material under the 42" pipe.
   c. Detail 2, Sheet C5-505, "Air Release & Access Manhole," shows a 2" corp stop for air release. These are intended to be manual air release valves for exhausting air upon initial filling of the pipeline or after maintenance has been performed and refilling the pipeline. The manhole structure will be checked periodically and pumped out with a portable sump pump as part of the normal plant maintenance program.
   d. See attached color coded yard piping diagram.

2. Midpoint Chlorination
   a. Four (4) new scales will be provided for monitoring chlorine usage from ton containers. Scales shall be as manufactured by Scaletron Industries Ltd. with a load range of 0 to 4000 lbs.
   b. The City has not been able to determine that the chlorine scrubber is a requirement of any applicable code. At this time, the City will not be installing the chlorine scrubber shown on the design drawings and will rely on the existing ventilation system to exhaust air from the Chlorine Storage Room.
   c. The existing ventilation in the Chlorine Storage Room was tested to have a capacity of 18.3 air changes per hour, or 0.305 air changes per minute. Therefore, one room volume air

change would take approximately 3.3 minutes with the current ventilation system. See attached test results. Due to the size of the existing Chlorine Storage Room, a ventilation system of 1 air change per minute is not practical. While the existing ventilation system capacity is less than 1 air change per minute, it appears to be in compliance with 10 State Standards as lesser rates may be considered in cases where 1 air change per minute is not appropriate due to the size of the room.

d. WTP staff will identify and inspect all proposed and existing piping and conduit wall penetrations in the Chlorine Storage Room and seal as necessary to prevent gas leakage into other parts of Pump Station No. 4.
e. Existing floor drains in the Chlorine Storage Room were for condensate from the old chlorine evaporator system. These drains will no longer be used and will be plugged by WTP staff.
f. WTP staff will attach new door sweeps with better seals at existing doors as required.
g. WTP staff will extend existing ventilation intake ductwork to finished floor level with 90-degree bends.
h. Per Addendum No. 1, an Anti-siphon / Back Pressure Valve and additional ball valve shall be added just prior to the trough wall penetration. The anti-siphon / back pressure valve shall be PVC and designed for use with chlorine systems. The valve shall be a LMI #35856, Walchem E90422, or engineer approved equivalent. The valve shall be installed between the two ball valves to allow for isolation during servicing. The valve shall be located above the high water level in the trough. The Contractor shall install a 1" drain line from the relief port to the finished floor elevation of the pipe gallery.

3. High Service Pump
   a. The new 16" pump control ball valve for HSP #1 replaces the existing pump control ball valve in kind and will operate in the same manner as the existing valve. The valve will act like a check valve upon emergency shutdown of the pump through the use of a hydraulic cylinder actuator that will automatically close the valve. The cylinder actuator uses hydraulic water system pressure to supply the energy required to close the valve.
   b. The existing HSP #1 is rated for 25 MGD at 185' TDH. The proposed replacement HSP #1 is rated for 15 MGD at 185' TDH, matching the head condition of the existing pump.
   c. Results from the City's hydraulic model were used to develop system curves for max day and average day, which were used to confirm pump selection. The proposed HSP #1 will operate on a VFD which can be adjusted during operation to meet various duty points depending on demand.

4. LOX/LIN Storage
   a. Nitrogen usage is calculated based on 2.5 % of the oxygen usage:

      2,833 ppd O_2 x 0.025 = 71 ppd N_2

5. Electrical Improvements
   a. The operation of the pumps is contained within a single switchgear at Pump Station No. 4. However, there will be a dual feed coming into the main plant switchgear that will supply redundant power to the plant, including Pump Station No. 4. There will also be two breakers

at the main plant switchgear that feed two different breakers at Pump Station No. 4. Therefore, any one point of failure will not take the system down.

Flint WTP Improvements
Phase II
Segments I-III
MDEQ Comments
March 19 , 2014

Segment 1 - Cut –in Piping

The detail shows air-release manholes with corp. stops? How will the air release operation be executed? Means to drain the manhole?

Written response needed.....

Segment 1 – WTP Rehab

1. **Raw Water Piping – Maintain back-up supply from Gen Co. during interim operation at C.S. #2. Sheet C5-102**

   54X42 cross (Sheet C5-501 & C5-101) only 6-inches – Support?

   Air-release manhole – same as Cut-in piping

   Current yard piping diagram?

Written response needed on the first 3 items. Yard piping diagram will be a work in progress.

2. **Mid-Point CL2 - Basis of design provided**

   - **Scale – use existing or proposed? If poposed - type, capacity**
   - **Scrubber?**
   - **Room air-exchange rate ?**
   - **Pipe penetrations – discuss protective seal**
   - **Floor drains – discuss**
   - **Door sweep - discuss**
   - **Scrubber piping – lower intake**

- **Check valve/anti-siphon at influent channel - include in final**

3. **High Service Pump**

   Will mechanical ball valve operate like a check valve in event of unexpected pump shut-down?

   TDH of current pump and proposed pump?
   Conformance of proposed pump TDH with system head curve?

   Written response needed.....

4. **LOX/LN Storage**

   Piping configuration clarified
   The LN calculation (71 ppd) is not clear. Is there a % concentration or transfer efficiency?

5. **Electrical improvements**

   Are operation of the pumps being split with the MCC or are multiple MCCs being provided?

   Written response needed.....

3. High Service Pump

   Will mechanical ball valve operate like a check valve in event of unexpected pump shut-down?

   TDH of current pump and proposed pump?
   Conformance of proposed pump TDH with system head curve?

4. LOX/LN Storage

   LOX & LN piping clarification – Sheet D2-102 & D2-601
   BOD for storage
   Ozone was designed at 4.0 mg/l max dose @ 36 MGD (Sec. 3.5 WTP BOD)

   Ozone max dose at 18.0 MGD is 650 Lbs/day

   How many GPD does this equate to?

5. Electrical improvements

   Are operation of the pumps being split with the MCC or are multiple MCCs being provided?

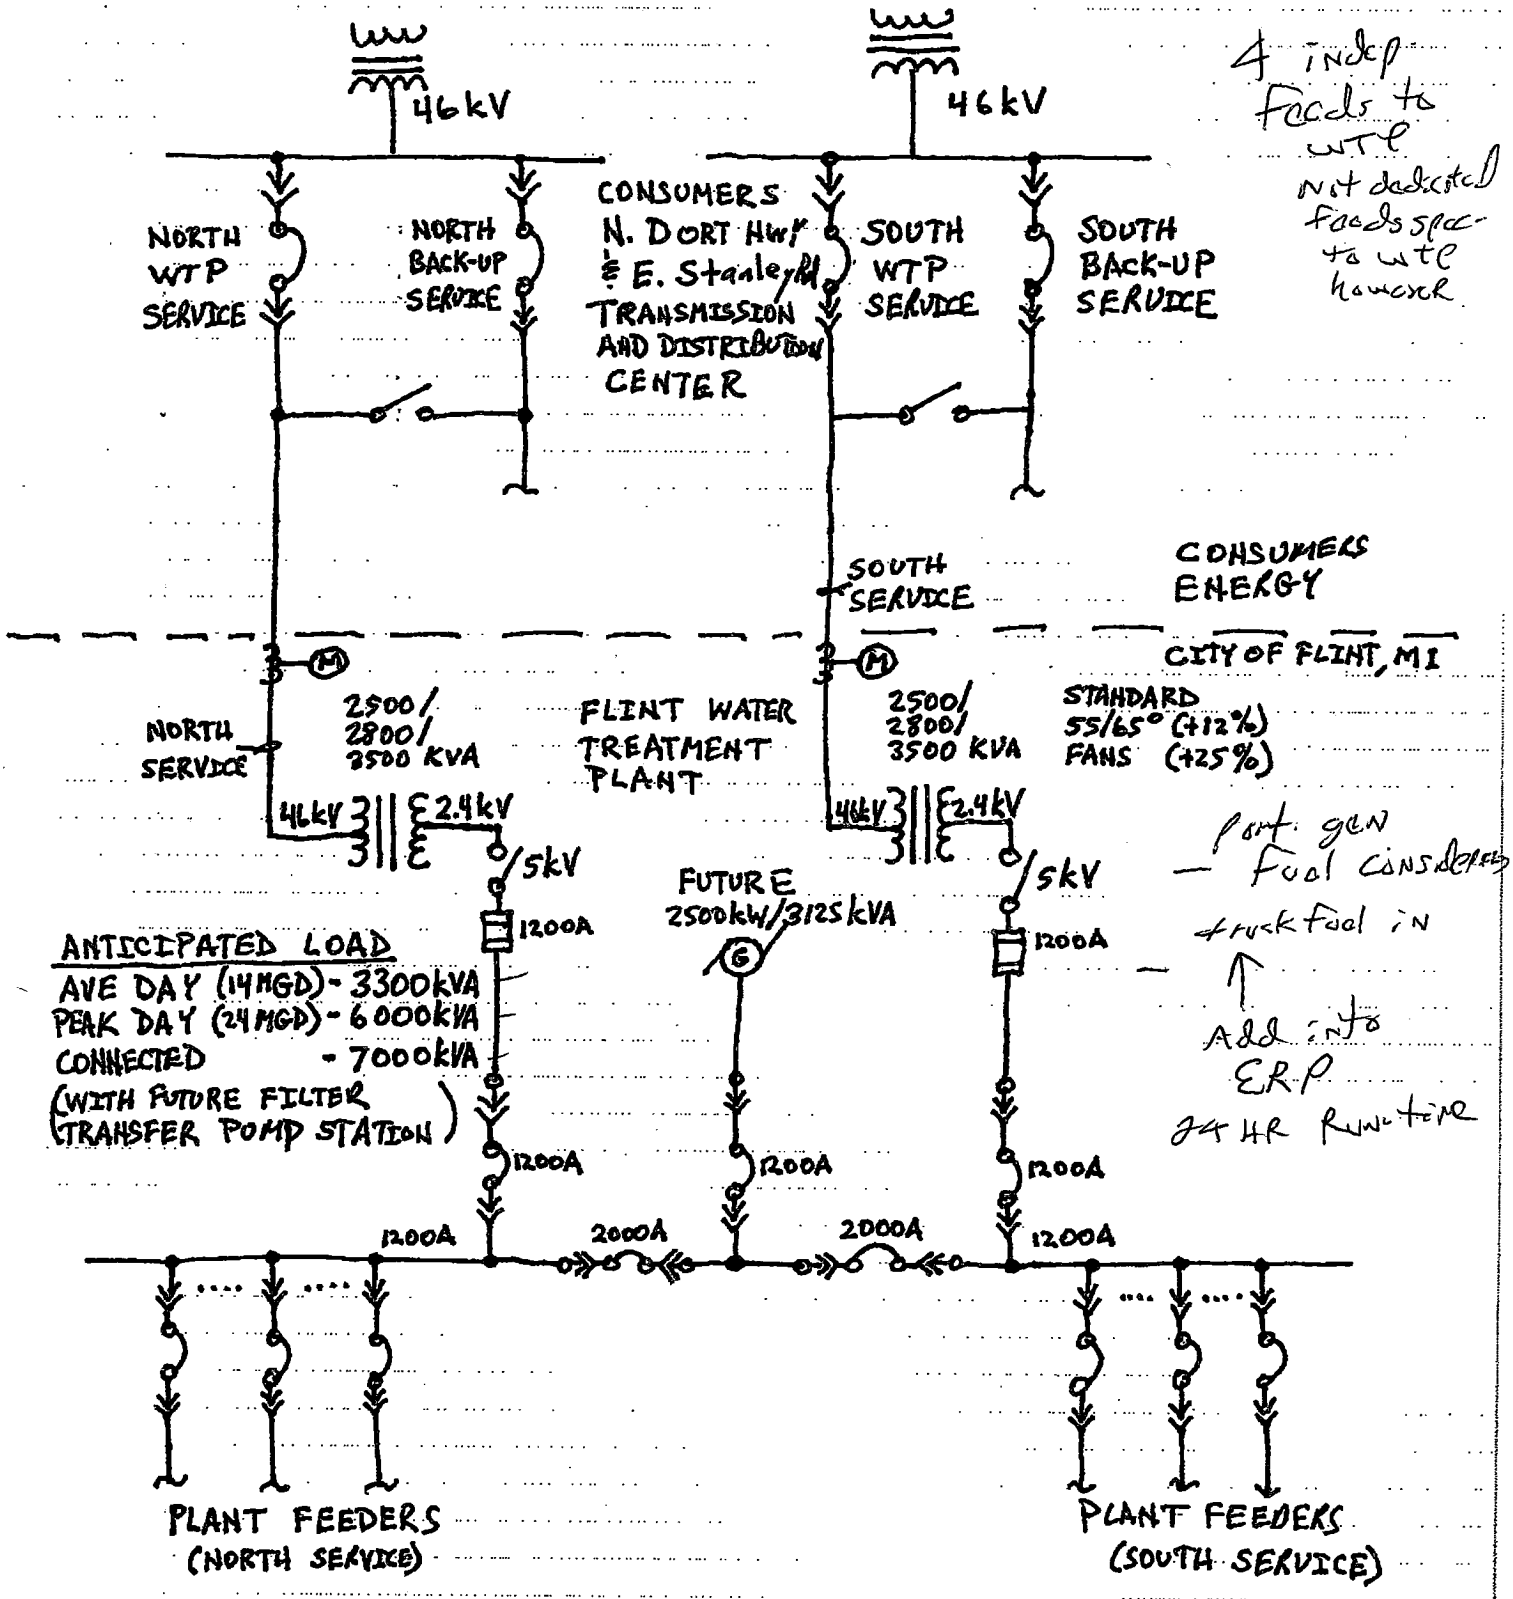
Mike

As you know, the Flint Water Plant (FWP) currently uses 2400V as primary power throughout the facility. All of the power feeders in the plant site are 5kV rated and it appears the existing switchgear is also rated at 5kV. Most of the major electrical improvements installed during Phase I were dual voltage (2400/4160) equipment in anticipation of the plant power being changed to 4160V in the future. However, this voltage conversion is not needed for the phase of work.

The current sub-station has two 2.5 MVA transformers running in parallel for a total capacity 5 MVA. These old transformers are not equipped with cooling fans. Based on the evaluation performed during the Phase II study, which was completed in 2003, the full connected load to these transformers is estimated to be 6.97 MVA while the estimated power load at 36-mgd is 4.22 MVA. Based on these estimates there is sufficient power for the plant with both sub-station transformers in service. Even though the transformers are owned by Consumers Energy, it could take weeks to replace one of these main transformers in the event of a unit failure, which will result in reduced treatment and pumping capacity. The sub-station switchgear was installed in 1960 and is antiquated and difficult to maintain.



Since the 2003 study, Flint's maximum day water demand has decreased to approximately 20-mgd, which has correspondingly reduced the estimated power load. At this time it is believed that two 2.0 to 2.5 MW transformers will be required to power the FWP to meet maximum day demand and one transformer will meet average day demand under emergency conditions. We are proposing to construct a new substation with two – 2.0 to 2.5 MW pad mounted transformers, along with substation switch gear, interconnected with one 2.0 to 2.5 MW intermittent duty diesel generator as shown below. This arrangement will allow the generator to backup either transformer to cover maximum day demands should one of the transformers or transformer feeds drop off line and to provide sufficient generation capacity to meet average day demands.

Howard Croft, DPW Director:

- Welcoming remarks, thank you to those in attendance.
- Recognize Elected Officials in attendance.
- Briefly describe recent work to finalize the preparations made to the plant.
- Provide quick facts about plant's capabilities and what they mean for Flint.

Darnell Earley, Emergency Manager:

- I want to highlight and recognize all the hard work done over the last two years that has led to this historic event, including the work of my predecessors Mike Brown and Ed Kurtz.
- I would also like to thank all of our staff, the Mayor, the City Council, Genesee County Drain Commissioner and his office, the MDEQ and Raftelis Financial Consultants for all their work in helping to identify KWA and the Flint River as the best choices for Flint's water needs. Their work is proof that this is the empirically correct course of action.
- The improvements that have been made to the plant over the past few years are in alignment with the City of Flint's strategic objectives, including the Master Plan and the Capitol Improvement Plan, which are steps toward ensuring a self-sustaining and financially healthy water and sewer system for Flint now and into the future.
- Having the resources of the river, the plant and eventually the KWA pipeline will position Flint to take advantage of increased economic growth and help to secure regional stability.

Mayor Dayne Walling:

- This is an historic moment for the City of Flint and I'm glad you could be here to witness it.
- Today we take a huge step forward in controlling the future of our most precious resource and utility by using the Flint River as our primary water source for the

first time in 50 years. This step will also allow Flint to have a permanent backup water source once the KWA pipeline comes online.

- The flipping of the switch we are here to witness today represents the true beginning of Flint's water independence.
- The Flint River was the first major asset to our community, so it is fitting that we return to its use for our city's benefit.
- Our water is safe, clean and tastes great; so come join me in a toast to Flint's future with water drawn and treated right here on this spot.

Toast with Treated Flint River water, followed by media Q & A period (approx. 15 min.)

DRAFT

Prysby, Mike (DEQ)

From: Brent Wright <bwright@cityofflint.com>
Sent: Thursday, June 19, 2014 10:55 AM
To: Prysby, Mike (DEQ); Michael Glasgow
Subject: CL2 Analyzer
Attachments: 20140619_102305.jpg

Mike the CL2 analyzer for PS#4 is already located in the suction well. The stand pipe was hooked up to the sample sink, that now is also pumped from the suction well. Attached is a picture of the tap and water line on the suction side of Pump #7. This water line is connected to a sample pump that pumps the water to the sample sink and the CL2 analyzer. I believe this set up is what you were looking for. If you have any questions please call me.

CITY OF FLINT WTP
TTHM Response Plan Meeting Minutes
Notes from the meeting shown in red, bold font
November 7, 2014 9:30 am

Discussion Topics

I. Introductions

II. Purpose/Overview

WG provided an historical review of Flint WTP since ~1999 through today including design and regulatory concerns. Phase I improvements from 1999-2005 were completed to allow the plant to operate as an emergency back-up to DWSD supply for a moderate time period (4-6 weeks). Phase II improvements are defined as improvements to allow the plant to operate full time, without DWSD supply. The ultimate supply will be Lake Huron water supplied through the KWA system. The Flint River is the current supply until KWA supply is available. A treatability study was completed in 2002 which evaluated full time supply from the Flint River and contains information that is directly relevant to today's operations.

A. KWA supply timing
   1. Expected completion fall 2016
B. TTHM high level samples
C. Levels at multiple sites indicate source / WTP issue
   1. Problem did not exist on Detroit water
   2. 8 sites likely to exceed OEL

III. Suspected Causes
   A. Source water
      1. TOC has remained consistent
      2. Turbidity has remained consistent
      3. pH has remained consistent
      4. Increase in total Coliform

Period	Turbidity NTU	TOC Mg/l	Alkalinity Mg/l	Hardness Mg/l	pH	Total Col. Count/day
2001 Apr–Oct	7.9	9.4	215	272	8.1	870-1230 (7300 max)
2014 May–Sept	8.1	10.3 5/22/14	205	250	8.1	1500-5000 (22,398 max)

   B. WTP operation
      1. Ozone feed not working properly
      2. Recent increased chlorine feed
      3. Coag or floc polymer aids might not be optimized
   C. Distribution problems
      1. Low flow
      2. Dead ends
      3. Too much storage
      4. **City has unlined CI**
      5. **Cedar Street and West Side pump stations do not pump into defined pressure districts and may be recirculating water**

6. **City has been repairing/replacing valves which could be resulting in flow pattern changes**

IV. Operational Evaluation Report Requirements
   A. Distribution system evaluation
      1. Distribution evaluation and modeling by others
      2. Storage capacity evaluation
      3. **The City is considering water model updates and new simulations to evaluate possible improvements**

   B. Source water evaluation
   C. Treatment evaluation
      1. Jar testing
      2. No ozone piloting
      3. Experiment with coag and floc polymer aid dosages
   D. Timing / schedule

Letter from MDEQ states the report is to be submitted by 11/28/14. However, regulations state the public water supply has 90 days from the date of violation to complete the Operational Evaluation Report and Flint has technically not had a violation yet. The next sampling period is the 3rd week of November. SB stated the MDEQ would like to have a draft report by 11/28/14 that would not need to be entirely complete, but this would show a proactive approach by the City.

V. Possible Solutions
   A. Chlorine dioxide or chloramine

LAN believes there is a reasonable chance that chloramine would not be a strong enough disinfectanct but chlorine dioxide warrants further consideration.

   B. Decreased chlorine feed rate

A portion of flow through the WTP was being bypassed around the softening process and it was believed to be contributing to chlorine demand. The City has discontinued the bypass and it appears chlorine demand has dropped by 0.5 – 1.0 mg/l.

   C. pH adjustment
   D. Corrections/modifications to ozone

The City and LAN have looked at the ozone feed system and data suggests there is a problem though the exact issue is yet to be determined. Further investigation is planned as one high priority response.

   E. Coag & floc polymer aids (better TOC removal)

Jar testing is planned as part of the OER during which polymer aids will be further evaluated.

   F. Enhanced TOC removal with softening
   G. UV??? [with chlorine after for residual]
   H. Flushing to decrease water age?

The City is considering increased flushing to address both water age and rusty water.

   I. Lower storage tank high water levels (use less volume)?

VI. Other

- Chlorine demand through the filters is another concern. The City may shock the filters with high chlorine feed in an attempt to 'cleanse' them.
- Addition of flocculation and/or coagulation polymer feeds: MDEQ is open to the idea and would consider a letter submittal from the City listing the details in order to provide approval if the City wants to implement into the WTP process.
- The average flow through the WTP has fallen off from 18-19 mgd over the summer to ~14 mgd at this time.
- A TTHM limit violation is Tier 2 and will require the appropriate public notice.
- The City is currently achieving ~60% TOC removal.
- pH is currently 7.5-8.0 at WTP effluent.
- Costs to reconnect to DWSD supply have become prohibitive as a viable solution: $4 Million start up fee + $900,000 monthly flat fee + usage charges.

DEPARTMENT OF ENVIRONMENTAL QUALITY

GOVERNOR'S OFFICE BRIEFING PAPER
CITY OF FLINT DRINKING WATER

What contributed to the Boil Water Advisories in the city of Flint?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWAs) in the city of Flint during August and September 2014. While use of the Flint River has increased the amount of natural organic matter in the city's water, the Flint Water Treatment Plant (WTP) has performed well above treatment requirements for organic carbon removal. In addition, less than 20 percent of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the city, rather than in such a localized area.

The city's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the city's over 550 miles of water mains are now over 75 years old and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior, leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The city has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses, and industrial property. Declining water use leads to excess residence time within the city's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the city has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The city, which historically has unaccounted water losses of over 30 percent, has seen even greater losses since February 2014 due to an increase in cold weather-related water main breaks and leaks. The city lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWAs were found to be closed during the city's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure. One of these valves has remained broken.

The BWAs also occurred during the warmest and, for 2014, relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

Process for Issuance and Cancelation of a Boil Water Advisory

There are a number of conditions that can trigger BWAs. This includes the following:

- Bacteria Monitoring Detections
- Bacteria Standards Violations
- Treatment System Failures
- Waterborne Disease Outbreaks
- Loss of System Pressure
- Water Main Breaks
- Other Interruptions in Service

The Department of Environmental Quality (DEQ) has developed a policy and procedure regarding BWAs to help guide staff, provide consistency, and maintain public health. A PDF of Policy and Procedure No. ODWMA-399-022 is being forwarded with this briefing paper.

BWAs may be self-initiated by the water system, issued collaboratively in consultation with the DEQ, or when necessary mandated by the DEQ. Requesting customers to boil the water when bacterial contamination has occurred provides an added barrier of public health protection.

The BWAs that recently occurred in the city of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the city of Flint collaboratively in consultation with the DEQ.

Current regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the U.S. Environmental Protection Agency, have been in effect since 1990, and were incorporated into the Michigan Safe Drinking Water Act, 1976 PA 399, as amended. There are a variety of bacteria, parasites, and viruses that can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for total coliform and *E.coli*. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system minimizes the likelihood that pathogens are present. *E.coli* is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for a period of 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

Recent History of the City of Flint Water System

Historically, the city of Flint had been a customer of the Detroit Water and Sewerage Department (DWSD) while simultaneously maintaining the Flint WTP to provide emergency backup service using the Flint River. The WTP performed quarterly test operations to maintain readiness and was utilized twice in 2009, supplying water once for 2 days and the other for 3 days.

In April 2013 the city of Flint notified the DWSD that it would be terminating service in the future and contracting for raw water service from the Karegnondi Water Authority (KWA). Work on the KWA pipeline from Lake Huron broke ground in June 2013 and is expected to be completed with connection in late 2016.

In August 2013 Rowe Professional Services Company completed an engineering proposal for improvements to the Flint WTP that would allow continuous operation of the WTP utilizing the Flint River in lieu of continuing service from the DWSD until completion of the KWA pipeline. In March 2014 the city of Flint entered into a Consent Agreement with the DEQ regarding the Flint WTP's lime sludge facility. In April 2014 the DEQ issued a construction permit for improvements to the Flint WTP. On April 25, 2014, the city of Flint began continuous operation of the WTP, using water from the Flint River and discontinued the purchase of water from the DWSD.

A BWA was issued for August 15-20, 2014, for a portion of the city of Flint due to localized detections of total coliform and *E.coli* bacteria. Another BWA was issued for September 5-9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the city of Flint. The advisory covered an area of approximately six square miles. The city of Flint has a total land area of just over 34 square miles.

While many of the BWA contributing factors listed above require long-term solutions, the city has taken operational steps to limit the potential for a BWA to reoccur. The city has increased flushing of water mains to limit residence time, maintain disinfectant residual, and help remove buildup and deposits within the piping. The city is boosting chlorine disinfectant residual at locations in the distribution system as needed. The city continues to investigate water leaks and water main breaks and the status and condition of system valves.

Flint, Michigan 48505

9/10/14
TTHM OEL
Exceeds MCL

SUBJECT: Compliance Communication
Total Trihalomethane Operational Evaluation Requested

Under the Stage 2 Disinfectants and Disinfection Byproduct Rule, the City of Flint has been required to collect samples for the analysis of Total Trihalomethane (TTHM) and Haloacetic Acids (HAA5) at eight sites within the City's water distribution system. The City has completed two quarterly monitoring periods since changing its source water to the Flint River effective April 25, 2014.

Normally an Operational Evaluation Level (OEL) would be calculated in accordance with the Michigan Safe Drinking Water Act, Public Act 399, 1976, as amended, Administrative Rule 7196 (R 325.107196), each quarter once three quarters of results have been obtained and compared with the respective maximum contaminant level (MCL) for TTHM. Normally the calculation would be made as follows:

(2 x current quarter + sum of 2 previous quarters) divided by 4

As the City of Flint currently has only two quarters of data, the calculation has been modified as follows:

(2 x current quarter + previous quarter) divided by 4

The resulting OEL for each site is listed in the table below. All results are in parts per billion (ppb):

	TTHM			HAA5		
	5/21/14	8/21/14	Mod. OEL	5/21/14	8/21/14	Mod. OEL
DBP1 McDonalds 3719 Davison	162.4	145.3	113	64	43	38
DBP2 Liquor Palace 822 S. Dort Highway	111.6	112	84	52	40	33
DBP3 North Flint Auto 3302 S. Dort Highway	96.5	127.2	88	48	31	28

Briefly Message to Gov

Current sitx

Process

History

↓

Summ. w. 3 points

1. Zoning site Dw
2. Procedure w. Plat - DEL
3. Engage locals

As shown in the table above, even with this less restrictive modified method, six of the City's eight sites already exceed the OEL limit of 80 ppb for TTHM. In addition, the City's two other sites are both more than 95% of the TTHM OEL limit.

The MCL for TTHM and HAA5 is based on a locational running annual average for each site, essentially the average at each site over the four previous quarterly monitoring periods. However, with TTHM levels of this magnitude, it is likely the MCL will be exceeded for at least one of these eight sites from just three quarters of monitoring results. For TTHM, four quarters at the MCL of 80 ppb (4 x 80) would provide 320 ppb allowable. As an example, site DBP1 through just two quarterly monitoring periods has a total of 307 ppb (162+145), leaving only 13 ppb over two more quarterly monitoring periods to maintain compliance with the MCL.

Therefore, this office is requesting the City of Flint complete an Operational Evaluation in accordance with Administrative Rule 719l (R325.10179l). The Operational Evaluation Report shall be submitted to this office no later than November 28, 2014. The report shall not be limited in scope and shall include the following:

Examination of Treatment Operational Practices
- Changes in source water quality
- Treatment changes
- Storage tank operations
- Excess storage capacity
- Treatment problems that contribute to TTHM formation

Examination of Distribution Operational Practices
- Storage tank operations
- Excess storage capacity
- Distribution system flushing

The report shall also include steps the City could consider to minimize future exceedances.

Additional guidance on completing the Operational Evaluation Report, including a number of forms that can be used to gather and evaluate water system information is provided in the United States Environmental Protection Agency's (U.S. EPA) Operational Evaluation Guidance Manual. This document is available on the U.S. EPA's website at the following link:

http://www.epa.gov/ogwdw/disinfection/stage2/pdfs/draft_guide_stage2_operationalevaluation.pdf

Be advised, failure to submit an Operational Evaluation Report by this deadline is a reporting violation subject to Tier 3 Public Notification.

The OEL is an indicator of operational performance. The water system must take proactive steps to be able to comply with the MCL's for TTHM and HAA5. While it is recognized that removal of Total Organic Carbon disinfection byproduct precursors as part of the treatment process has performed above minimum removal requirements under the treatment technique, around 4 parts per million of organic carbon are still present in the treated water and may be leading to additional TTHM formation in the City's distribution system.

While health effects associated with disinfection byproducts contaminants are based on chronic exposure, the City has available alternatives that must be considered to achieve compliance with this drinking water public health standard.

To:	Shekter Smith, Liane (DEQ)
Cc:	Bloemker, Jon (DEQ); Busch, Stephen (DEQ)
Subject:	Flint WTP

Liane,

Eric Kline from the Department of Treasury, Office of Fiscal Responsibility returned my call with several questions concerning the operating requirements of the Flint WTP. Eric is aware that Flint has been a DWSD customer since the 1960s and that the city is currently at the crossroads of either remaining a customer of DWSD (either blending or total DWSD purchase) or breaking away from DWSD and committing to the KWA project. The Department of Treasury is currently investigating these options to determine the best long term financial option for Flint.

Eric's first question:

Are there any scenarios where the DEQ would allow Flint to totally decommission their WTP?

My response first included a brief discussion of the history of the Flint WTP and the city's obligation to maintain and operate the facility on a test-run basis to provide an adequate back-up supply of water to the city and Genesee County in the event that the supply of water from Detroit (single transmission line) is interrupted. Eric appeared to already have a good understanding of this topic. Next, Flint could only decommission their WTP if the city was to establish 2 independent sources of drinking water – either DWSD with KWA (back-up) or vice versa. This option would be difficult since KWA's intention is to sell untreated water to members of the authority including Flint. In this scenario, Flint may need to become a customer of Genesee County, not KWA. Otherwise, the city would need to establish 2 independent sources from Detroit.

Q2: Does Genesee County currently have a water treatment facility?
A2: Genesee County currently purchases water from Flint as a wholesale customer; thus the county does not have their own
WTP at this time.

Q3: Does the DEQ take any stance on the possibility of Flint blending treated water from its own WTP?

A3: The city of Flint may elect to utilize their WTP for the blending of treated water from the Flint River with water purchased from DWSD or KWA provided that all applicable drinking water standards are maintained. The city would also be encouraged to produce water of the same aesthetic quality to the water currently purchased from DWSD. Thus, DEQ does not have an objection to the option of blending.

Eric indicated that he may contact me again if he has any further questions of which I will provide the necessary updates.

City of Flint Water System Discussion
Water Treatment Plant/Water Distribution System
2/10/2011

WATER TREATMENT PLANT:

Prelim eng report

1. **Hamilton Dam – Project status?**

   - **Preliminary design – conforms to low service pumping needs?**

2. **Water Treatment Plant Test Runs - Test runs performed in 2010 - reports?** can't get into office → Aug 10 - Run; Mar 10 - Run; April 10 - Run

   No. of test runs with intermediate CL2?

   send us test reports

3. **High Service Pumping - long range future use level identified?**

4. **Operator Certification - OIC oversight at WTP during;**

   WTP downtime -
   Routine test-runs -
   Emergency Operation -

   Staff from Genesee County – memo of understanding?

5. **Water System Contingency Plan/WTP SOP**

   review of both documents with comments

   ERP required in place of Contingency Plan

   → entity looking ERP only - wide

   But will send ERP template

look on 72 — same area Genesee Rd near
draining into Nearby Storm Curbs

Pipeline issues in 2010? Potential problems in 2011 or beyond?

→ Fax all Bay Rd Ltrs to M. Bloom (6a) 793-5758

6. WTP Sludge disposal at Bray Road – city's intentions? - based on EMRD's requested work plan…

No talks yet on this
City needs to address EMRD's requests / new items for WTP
what is the DNRE waiting on to do on the city's part?

WATER DISTRICTION

7. Pumping Stations

- Resubmittal for DWRF in 2011
- Seasonal interim switchgear upgrades

Cedar Street/Torrey Road/Westside pump stations

Status of upgrades at each station? — revised into NOW DWRF APPL in SPR 11

8. Reliability Study

Phase II Study – status? — At point now for Alternate for CIP now plan on how to sequence with to get Phase II completed

Amended Phase I document? — Amend Phase I & submit w/ Phase II

Model up & running
Waiver are set-up
Hydr are all stored & done

Global Items: stop-more CIP & evaluated with Fitch as it becomes Genesee

Karegnondi Water Authority/DWSD Second Pipeline

Flint's capability to participate? Track $ &
Additional improvements at WTP? — Focusing on
New contract with DWSD? —
Genesee County Relationship/Contract? —

2011 Needs Survey - reliability study to be used as source for independent documentation.

The GLOBAL ISSUE

Blending — Not Benefit due to DWSD's toady to serve charge — would cost us more to blend

Break from DWSD — 5-6 yrs

* Regional car if Karagindi * Eason's thoughts

City wants to support it's own

Not Dep. on DWSD — & invest its own WTP

focus on River, if Karagindi

* Do will Bond tied to pub. improve fund hoping for

→ Soma to invest in WTP Eason's WTP

Subject: Fluoride application at The Flint Water Treatment Plant

Gentleman per our earlier conversation Flint WTP would like to suspend the application of Fluoride in its treatment process until the first part of June, 2014. With this being our first month of operation and 2/3's of the operation staff in training, I feel the citizens of Flint would be better served if the operation staff were able to just concentrate on primary drinking water standards at this time. Please respond with any thoughts or concerns you may have regarding this matter.

Thank you

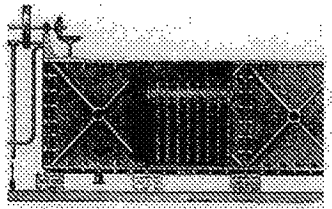
1/6: Mike P. - Arthur Woodston – resident – general questions, invite to res. Mtg
1/6: Mike P. - Bradley - resident – ok to boil water for baby formula bottle?
1/6: Mike P. - Raimy Elley – resident – gen info., most upset on city's delay to notify
1/6: Mike P. - Reps. Sheldon Neeley and Phil Phelps – update State Reps for Flint Districts on TTHM issue. Richard Benzie and Sarah Howes participated.
1/6: Steve B. – Cheryl Wormsman – friend of Flint resident- general questions/concerns

1/8: Mike P. – Sandra Wilkes – resident – excessive cost for poor quality, who can force Flint to re-connect to Detroit…
1/8: Mike P – Arthur Woodston (2nd call). Recc. Not to drink water from doc…where do I go?

1/9: Mike P – Patricia Warner – Gen. info…excessive cost/poor WQ, better comm. from city needed
1/9: Mike P – Jeanette Doll (DTMB) – left message to call me back concerning alt. water for state Bldg.. in Flint. Answer ? pertaining to future TTHM results and PN. Call most likely to ensue on Monday 1/12. **** Completed call w. Jeanette on 1/12 and answered her question pertaining to future TTHM monitoring and how it will pertain to compliance.**
1/14: Mike P – Mindy Blasdeel – resident – daughter with skin rash since being on DWSD water, On-going bladder infection – Mindy was at physician office and call was cut short. I will contact Mindy tomorrow to finish our call.
1/20: Mike P- Paris Glazer (Assoc. Attorney – LaRose Bosco law firm) – determining validity for Case claim (Fed. Statute claim) for Flint residents. Are there any way(s) to remediate high TTHM levels before KWA? Possible FOIA…..

CITY OF FLINT
WATER SOFTENING TRAINING



September 10, 2013

Lockwood, Andrews & Newnam, Inc.

Sept 26 G
Softening
training @ EAP

WATER SOFTENING

- Process of using quicklime and soda ash for hardness removal was first used in 1841.
- Called the Porter-Clark method
- Chemical equations and dosage calculation methods are still used today.
- Driven by brewers and distillers because hard waters interfered with fermentation and facilitated the growth of undesirable organisms.
- Determined with a soap test.

18—Porter-Clark Water softening and Filtering

THE WORD HARDNESS, IMPLYING THE HARD OR HARSH FEELING TO THE HANDS, IS THUS USED IN A PURELY TECHNICAL AND COMMERCIAL SENSE.

S. RIDEAL, D. SC. 1902

imp. equiv

↓

Ca mg/l * 2.5 = mg/l of Ca Hardness as CaCO3

Mg mg/l * 4.12 = mg eqv as CaCO3

TH of H

Softening Terms

- What Causes Hardness in Water
  - Divalent Metallic Cations
    - Primarily Calcium (Ca^{++}) and Magnesium (Mg^{++})
    - (Strontium (Sr^{++}), Iron (Fe^{++}), Manganese (Mn^{++}))
    - Largely Derived From Contact with Soil and Rock
- Types of Hardness
  - Calcium
  - Magnesium
  - Carbonate (CH)
  - Noncarbonate (NCH)
  - Negative Noncarbonate (NNCH)
- Total Hardness = Calcium Hardness + Magnesium Hardness
- Reported as mg/l as $CaCO_3$

Alkalinity

- What is Alkalinity
  - Water's Ability to Buffer Radical pH Changes or its Capacity to Neutralize Acid
- Types of Alkalinity In Water
  - Bicarbonate (HCO_3)
  - Carbonate (CO_3)
  - Hydroxide (OH)
- Determined in the Lab by Titration with H_2SO_4
- Two Indicators are Used – Phenolphthalein & Methyl Orange
- Two Alkalinity Values can be Included on Lab Report
  - Total (T) and Phenolphthalein (P)
- Also Reported as mg/l as $CaCO_3$

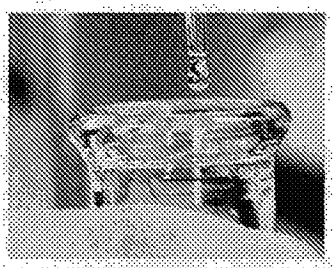
Ca^{+2} combined with HCO_3^- → CARB HARD

$+2 + \underbrace{C}_{\text{needs 2 of em}}$

$Ca(HCO_3)_2$

Mg^{+2} CO_3^{-2} → 1:1

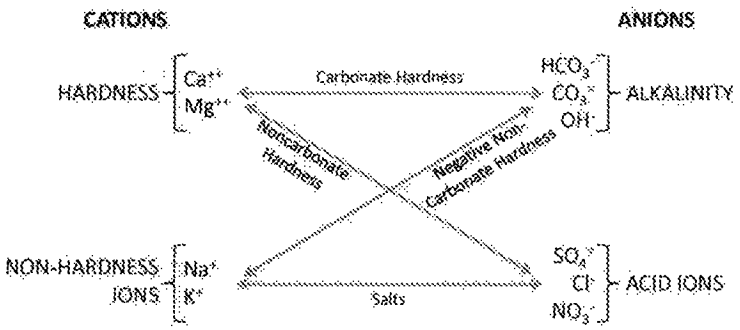
$MgCO_3$ → CARB HARD



How to determine which type of alk. you have Based on P alk & T alk

Alkalinity Relationships

plug & chug



Hydroxide Alkalinity as	Carbonate Alkalinity as	Bicarbonate Alkalinity as
P=0	0	T
P<1/2 T	0	T-2 P
P = 1/2 T	0	2 P
P>1/2 T	2 P - T	2(T - P)
P=T	T	0

KEY: P = phenolphthalein alkalinity; T = total alkalinity

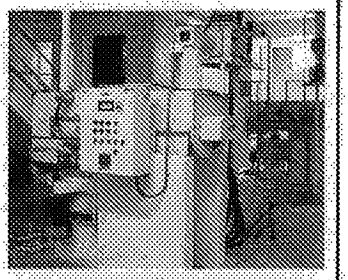
Negative Non-carbonate

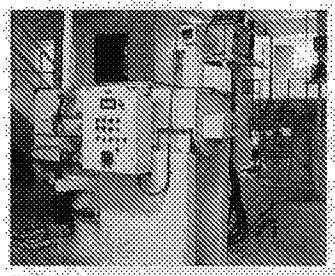
to remove hardness
Add hardness
to remove hardness



Chemical Softening Process

Add Hardness to Remove Hardness

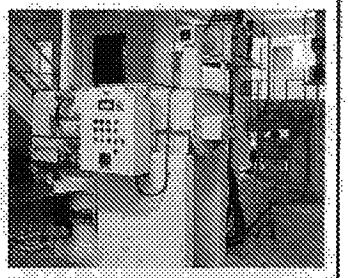
Chemical Softening Process



- Takes advantage of low solubilities of certain calcium and magnesium compounds to remove these cations from solution

Add Hardness to Remove Hardness

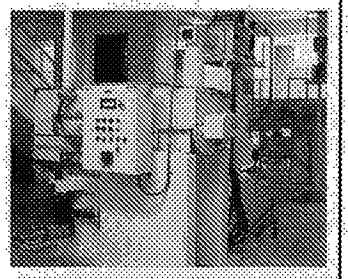
Chemical Softening Process



- Takes advantage of low solubilities of certain calcium and magnesium compounds to remove these cations from solution
- Calcium is precipitated as calcium carbonate by increasing the carbonate concentration above the solubility point

Add Hardness to Remove Hardness

Chemical Softening Process

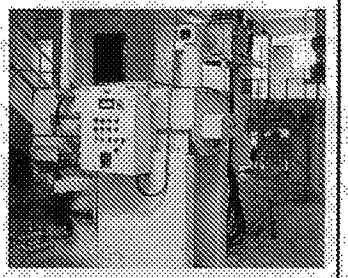


- Takes advantage of low solubilities of certain calcium and magnesium compounds to remove these cations from solution
- Calcium is precipitated as calcium carbonate by increasing the carbonate concentration above the solubility point
- Magnesium is precipitated by increasing the hydroxide concentration

Add Hardness to Remove Hardness

Chemical Softening Process

- Takes advantage of low solubilities of certain calcium and magnesium compounds to remove these cations from solution
- Calcium is precipitated as calcium carbonate by increasing the carbonate concentration above the solubility point
- Magnesium is precipitated by increasing the hydroxide concentration
- Calcium hydroxide - $Ca(OH)_2$ (hydrated lime)



Add Hardness to Remove Hardness

pre to 5 Sulcomy CO2 - must neutralize
6 w hr nst
6 w 35 kg 50-60 mg/g → first
5 w 3 10 mg/e → Avoid

Chemical Softening Process

- Calcium Oxide - CaO (pebble, slake or quick lime)
- $CaO + H_2O \rightarrow Ca(OH)_2 + heat$

- Carbon Dioxide (CO_2)
  - Groundwater – 50 mg/l
  - Surface water - < 10 mg/l
  - $\log CO_2 = 6.338 + \log ALK(T) - pH$
  - $CO_2 + Ca(OH)_2 \rightarrow CaCO_3\downarrow + H_2O$

ADD HARDNESS TO REMOVE HARDNESS

Chemical Equations

- CARBONATE HARDNESS IS PRECIPITATED AS CALCIUM CARBONATE OR MAGNESIUM HYDROXIDE BY THE ADDITION OF LIME AS FOLLOWS:
  - $Ca(HCO_3)_2 + Ca(OH)_2 \rightarrow 2CaCO_3\downarrow + 2H_2O$
  - $Mg(HCO_3)_2 + 2Ca(OH)_2 \rightarrow 2CaCO_3\downarrow + Mg(OH)_2\downarrow + 2H_2O$
- NONCARBONATE CALCIUM HARDNESS IS PRECIPITATED AS CALCIUM CARBONATE BY THE ADDITION OF ~~[illegible]~~ soda ash FOLLOWS:
  - $CaSO_4 + Na_2CO_3 \rightarrow CaCO_3\downarrow + Na_2SO_4$

$CO_2 = 10^{(6.35 + \log Alk - pH)}$

Use on calc

10^x

Add H_2O 1 mL to 1 mL from CO_2

Chemical Equations

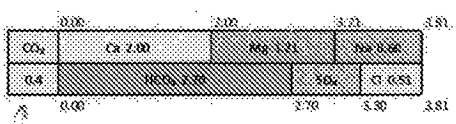
- NONCARBONATE MAGNESIUM HARDNESS IS PRECIPITATED AS MAGNESIUM HYDROXIDE BY THE ADDITION OF LIME WITH THE CONCURRENT PRODUCTION OF CALCIUM SULFATE, WHICH IN TURN IS PRECIPITATED AS CALCIUM CARBONATE WITH THE ADDITION OF SODA ASH AS FOLLOWS:

$$MgSO_4 + Ca(OH)_2 \rightarrow Mg(OH)_2\downarrow + CaSO_4$$

$$CaSO_4 + Na_2CO_3 \rightarrow CaCO_3\downarrow + Na_2SO_4$$

- Softened water is saturated with calcium carbonate and will have a high pH and must be stabilized prior to filtration. Is usually accomplished with carbon dioxide and is referred to as recarbonization:

$$CaCO_3 + CO_2 + H_2O \rightarrow Ca(HCO_3)_2$$



Softening Calculations

Water Analysis

	CO_2	8.8	mg/l	Alk (T)	135	mg/l	as $CaCO_3$
cat	Ca^{++}	40	mg/l	Alk (F)	0	mg/l	as $CaCO_3$
cat	Mg^{++}	14.7	mg/l	SO_4	29	mg/l

Subject: RE: Director's visit to Flint

Ben ,

The Flint WTP is a 36 million gallon per day (MGD) facility (Flint River source) that underwent a $45 million rehabilitation project (completed in 2005) that allows the plant to function as an emergency back-up water supply for the city of Flint and Genesee County. The WTP is not operated on a routine basis ; however, the facility would be placed into emergency operation in the event that the single pipeline serving Flint (72-inch transmission main) from the Detroit Water & Sewerage Department (DWSD) were to fail. The MDEQ requires the city of Flint to conduct quarterly test runs to demonstrate that the WTP remains capable of producing treated water that meets the drinking water standards. The WTP will be conducting one of these test runs during the visit on June 29th.

The city is currently faced with the challenge of determining their future source of drinking water. Yearly wholesale rate increases from DWSD is making it increasingly more difficult for the city and its residents to afford the cost of water. Flint's long-term choices include the ability to fully utilize the WTP through blending treated water from the Flint River with water either purchased from DWSD or from Lake Huron through the Karegnondi Water Authority (KWA). The MDEQ does not object to the option of blending treated water; however, additional infrastructure will be needed at the Flint WTP. Finally, Flint would also have to "buy-in" to the KWA if they wish to purchase Lake Huron water for treatment.

The city is very aware of the need to commit to a new source of drinking water; however, given their current financial situation, it does not appear that the city can move forward towards establishing any binding commitments. It is possible that officials from city administration may attend the WTP tour and take the opportunity to express this concern with the Director.

Finally, the Flint WTP was placed into emergency operation in 2009 to mitigate two separate pipeline emergencies. The ability of the stand-by WTP to produce potable drinking water during these two events prevented a region-wide water emergency and maintained public health protection for over 100,000 people.

Finally – here's the address: 4500 North Dort Highway
Flint, Michigan 48505

Ok I need to pass on to the Director a short paragraph on this Facility along with the address. Also he would like a limited number of people on the visits.

Ben Hall

May 10, 2012

I received a media inquiry from Ms. Kristen Longley from the Flint Journal concerning the city of Flint and the direction(s) that they are investigating for their future source of drinking water. A summary of our discussion is provided below.

Q1. Have you been in contact or involved in discussions with the city of Flint concerning their future direction for drinking water?

A: Staff from the MDEQ and myself have been involved in several discussions with the city concerning this issue.

Q2: The city of Flint is considering various options for the blending of water. Does the DEQ support the blending of water?

A: The blending of treated water from the Flint WTP with water purchased from Detroit is a feasible option and would be allowed by the DEQ provided that the finished water quality distributed to the city Flint is comparable to the water currently purchased from Detroit.

Q3: Would it be feasible and/or ideal from the DEQ's standpoint for the city of Flint to blend up to three sources of water: Flint River, water from Detroit and water from the proposed KWA pipeline from Lake Huron?

A: It would be feasible to treat raw water from 2 sources and blend that one component of treated water from the Flint WTP with finished water purchased from Detroit ....again... provided that water which is distributed to the city of Flint is comparable in quality to the water currently purchased from Detroit.

Q4: How likely is it that the finished water quality will be acceptable?

A: The DEQ is confident that the Flint WTP can meet drinking water standards based on the degree of treatment at the WTP. The WTP has also demonstrated the ability to treat Flint River water (as a sole source) during emergency operation and yet maintain primary drinking water standards.

Q5: Is the DEQ concerned about the capacity of the Flint River?

A: Capacity of the Flint River could pose some concern if the city were to utilize the Flint River as it sole source. As the component of use of the Flint River decreases with increasing use of KWA and/or Detroit water, available source capacity will be less of a concern.

Q6: What regulatory role do you have with the city of Flint?

A: I have regulatory oversight of the Michigan Safe Drinking Water Act and Rules as it pertains to public water supplies, including the city of Flint.

End of inquiry

MEMORANDUM

DATE: November 7, 2011
TO: Liane Shekter Smith, John F. O'Brien, and David Jansen
FROM: John C. O'Malia, P.E.
SUBJECT: Response to MDEQ Email to John O'Brien dated October 10, 2011

I have discussed the referenced email with Genesee County Division of Water and Waste Services' staff and wish to confirm the following:

1. County elections are Tuesday, November 8, 2011,

2. Karegnondi Water Authority (KWA) should be able to finalize contracts with potential members by the end of December. This will define the project size in that each member will select their flow contract amount. This will then define the actual project size versus what was proposed in the Lake Huron Water Supply Study Report dated 2009,

3. The finalization of items 1 and 2 above should allow KWA to then define the project size by the end of December 2011,

4. With the project defined, scheduling a meeting with MDEQ staff in early January 2012 would be appropriate,

5. There have been discussions with City of Detroit DWSD, on many technical issues regarding utilizing/purchasing some of the DWSD physical facilities. Although technical progress is being made, any purchasing of physical assets will have to be approved by DWSD and City Council. So, final agreement is sometime in the future and, that again, could impact project size, scope and schedule,

6. At the MDEQ meeting, we can fully inform you and staff of the DWSD discussions and how the impact on the project size and scope. If an agreement is reached regarding DWSD assets, this will impact final design. However, the 2009 Lake Huron Study must be updated once the project size is known. Therefore, the study will be updated and ready for review approximately six months after community contracts for volume are signed.

7. It is likely that the KWA project could move quickly into design. That being the case, we wish to work closely with MDEQ to keep communications open with timely meetings to resolve issues and eliminate long review times. We recognize the project size and substantial effort required by all, so it is our intent to minimize conflicts and resolve issues quickly to move the project forward,

8. We also recognize the diversity of project physical location(s). That impacts MDEQ review staff location(s) and we will be sensitive to that issue. This will also be a topic we wish to discuss in our meeting with you and staff.

We appreciate your interest in defining the KWA Project. We also look forward to resolving Project Scope and Schedule and will keep you informed on progress as it evolves.

Dear Mr. O'Brien:

SUBJECT: Water Withdrawal Permit Number 2009-001

This is in response to your May 14, 2012, request to modify Genesee County's large quantity water withdrawal permit number 2009-001. The permit to withdraw up to 85 million gallons of water per day for a community public water supply was issued on August 28, 2009, under the provisions of Part 327, Great Lakes Preservation, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended.

The requested changes to the permit include the relocation of intake cribs from approximately 3 miles offshore to 1.5 miles offshore, and the reduction in diameter of the intake line from 96 inches to 72 inches.

The requested design and construction changes do not alter the determination made by the Department of Environmental Quality (DEQ) during its review of the original water withdrawal permit application. In addition, public comments received, and consultation with the Great Lakes states and provinces did not raise any concerns about the requested changes. A revised permit indicating the new location of the intake cribs is enclosed.

If you have any questions regarding this correspondence or permit, or if there are any additional changes proposed to your project as described in the original permit application materials, please contact Mr. Andrew LeBaron, Surface Water Assessment Section, Water Resources Division, at 517-241-1435; or you may contact me.

REVISED LARGE QUANTITY WATER WITHDRAWAL PERMIT

Issued under Part 327
Great Lakes Preservation, of the Natural Resources and Environmental Protection Act
1994 PA 451, as amended

In accordance with Part 327, Great Lakes Preservation, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended (NREPA), authority is hereby given to withdraw water from the waters of the State of Michigan as described herein. This permit is issued in reliance on information supplied in the corresponding application and other information as may have been supplied by the permit applicant in support of that application.

PERMIT NUMBER: 2009-001

DATE ISSUED: August 28, 2009
DATE REVISED: August 14, 2012

Permittee Name and Address: Genesee County Drain Commission
Division of Water and Waste Services
G-4610 Beecher Road
Flint, Michigan 48532

Location Information

County where Water Withdrawal is Located: Sanilac County
Township Name, Town, Range, and Section: Worth Township, T9N, R17E, Sections 31 and 32

The activity authorized by this permit is subject to the following limitations and conditions:

Section A. Authorizations and Coverage Provisions

1. **Water Withdrawal is restricted to the following sources, locations, and rates above the baseline capacity established with the DEQ:**

Water Withdrawal Source	Latitude and Longitude (decimal degrees)	Withdrawal Rate
Lake Huron	43.1724; -82.4827	85 million gallons per day / 59,028 gallons per minute

2. **Approval Conditions**

a) The Genesee County Drain Commission must require as a condition of this authorization that all participating members of the Karegnondi Water Authority certify compliance with the environmentally sound and economically feasible water conservation measures applicable to the water user's sector under Section 32708a of Part 327 and posted on the DEQ Web site prior to commencing with the construction of any facilities necessary to implementation of the withdrawal. Certification shall be provided to Ms. Diana Klemans, Chief, Surface Water Assessment Section, at klemansd@michigan.gov; or DEQ, P.O. Box 30458, Lansing, Michigan 48909-7958.

b) A permit under the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), and rules, must be obtained prior to commencing with the construction of any facilities necessary to implementation of the withdrawal.

Section B. Reporting and Record Keeping

1. Environmental Impacts

The permittee is required to immediately contact Mr. Brian Rudolph, Saginaw Bay District Supervisor, at 989-894-6225 if an Adverse Resource Impact (ARI) occurs in association with the water withdrawal authorized by this permit. An ARI is defined in Section 32701(1)(a)(vii) of Part 327 as "Decreasing the level of a lake or pond with a surface area of 5 acres or more through a direct withdrawal from the lake or pond in a manner that would impair or destroy the lake or pond or the uses made of the lake or pond, including the ability of the lake or pond to support characteristic fish populations, or such that the ability of the lake or pond to support characteristic fish populations is functionally impaired."

2. Water Use Report

Water Use Reporting for a Public Water Supply is implemented through the annual reporting required under Act 399.

Section C. Liability

1. Noncompliance

Commencing the water withdrawal authorized herein confirms the permittee's acceptance and agreement to comply with all terms and conditions of this permit. Noncompliance with these terms and conditions, and/or the initiation of other regulated activities not specifically authorized by this permit, shall be cause for the modification, suspension, or revocation of this permit, in whole or, in part. Further, the DEQ may initiate criminal and/or civil proceedings to correct deficiencies, protect natural resource values, and secure compliance with law.

2. Limitations

This permit does not convey property rights in water or other real or personal property, authorize any injury to private property or invasion of public or private rights, or waive the necessity of obtaining any other applicable federal, state, or local permit or approval.

3. Indemnification

The permittee shall indemnify and hold harmless the State of Michigan and its departments, agencies, officials, employees, agents, and representatives for any and all claims or causes of action arising from acts or omissions of the permittee, or employees, agents, or representatives of the permittee, undertaken in connection with this permit. This permit shall not be construed as an indemnity by the State of Michigan for the benefit of the permittee or any other person.

MICHIGAN DEPARTMENT OF ENVIRONMENTAL QUALITY

PERMIT APPLICATION FOR WATER SUPPLY SYSTEMS

(CONSTRUCTION - ALTERATION - ADDITION OR IMPROVEMENT) AS DESCRIBED HEREIN

Required under the Authority of 1976 PA 399, as amended

This application becomes an Act 399 Permit only when signed and issued by authorized Michigan Department of Environmental Quality (DEQ) Staff. See instructions below for completion of this application.

1. **Municipality or Organization, Address and WSSN** that will own or control the water facilities to be constructed. This permit is to be issued to: Genesee County Drain Commissioner Division of Water and Waste Services G-4610 Beecher Road Flint, MI 48532 **WSSN:** 02615	Permit Stamp Area (DEQ use only) MICHIGAN DEPARTMENT OF ENVIRONMENTAL QUALITY PERMIT NO. W 122056 AUG 21 '12 SLA EXAMINED AND APPROVED FOR COMPLIANCE WITH ACT 399, P.A. 1976	
2. **Owner's Contact Person** (provide name for questions): Contact: John O'Brien, PE Title: Director Phone: (810) 732-7870		
3. **Project Name** (Provide phase number if project is segmented): Lake Huron Water Supply Initiative Contract S-4000 Water Supply Intake	4. **Project Location** (City, Village, Township): Worth Township	5. **County** (location of project): Sanilac

☐ **If this box is marked see attached special conditions.**

Instructions: Complete items 1 through 5 above and 6 through 21 on the following pages of this application. Print or type all information except for signatures. Mail completed application, plans and specifications, and any attachments to the DEQ District Office having jurisdiction in the area of the proposed construction.

Please Note:

a. This **PERMIT** only authorizes the construction, alteration, addition or improvement of the water system described herein and is issued solely under the authority of 1976 PA 399, as amended.
b. The issuance of this **PERMIT** does not authorize violation of any federal, state or local laws or regulations, nor does it obviate the necessity of obtaining such permits, including any other DEQ permits, or approvals from other units of government as may be required by law.
c. This **PERMIT** expires two (2) years after the date of issuance in accordance with R 325.11306, 1976 PA 399, administrative rules, unless construction has been initiated prior to expiration.
d. Noncompliance with the conditions of this permit and the requirements of the Act constitutes a violation of the Act.
e. Applicant must give notice to public utilities in accordance with 1974 PA 53, (MISS DIG), being Section 460.701 to 460.718 of the Michigan Compiled Laws, and comply with each of the requirements of that Act.
f. All earth changing activities must be conducted in accordance with the requirements of the Soil Erosion and Sedimentation Control Act, Part 91, 1994 PA 451, as amended.
g. All construction activity impacting wetlands must be conducted in accordance with the Wetland Protection Act, Part 303, 1994 PA 451, as amended.
h. Intentionally providing false information in this application constitutes fraud which is punishable by fine and/or imprisonment.
i. Where applicable for water withdrawals, the issuance of this permit indicates compliance with the requirements of Part 327 of Act 451, Great Lakes Preservation Act.

6. **Facilities Description** – In the space below provide a detailed description of the proposed project. Applications without adequate facilities descriptions **will be returned.** SEE EXAMPLES BELOW. Use additional sheets if needed.

78" water supply intake extending approximately one mile into Lake Huron. Two timber intake cribs are included on the intake pipline. The intake pipline is designed to provide a capacity of 85 mgd. Each intake crib has a capacity of 60 mgd. Chemical piping is provided to supply a chlorine solution to diffusers in each intake crib for zebra mussel control. A 30-foot diameter concrete junction chamber is located approximately 200' west of M-25 and 1,000' north of Fisher Road. The west end of the intake pipeline is located at the junction chamber. A valve is provided in the junction chamber on the intake pipeline.

EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES	
Water Mains	500 feet of 8-inch water main in First Street from Main Street north to State Street. OR 250 feet of 12-inch water main in Clark Road from an existing 8-inch main in Third Avenue north to a hydrant.
Booster Stations	A booster station located at the southwest corner of Third Avenue and Main Street, and equipped with two, 15 Hp pumps each rated 150 gpm @ 200 feet TDH. Station includes backup power and all other equipment as required for proper operation.
Elevated Storage Tank	A 300,000 gallon elevated storage tank located in City Park. The proposed tank shall be spherical, all welded construction and supported on a single pedestal. The tank shall be 150 feet in height, 40 feet in diameter with a normal operating range of 130 – 145 feet. The interior coating system shall be ANSI/NSF Standard 61 approved or equivalent. The tank will be equipped with a cathodic protection system, and includes a tank level control system with telemetry.
Chemical Feed	A positive displacement chemical feed pump, rated at 24 gpd @ 110 psi to apply a chlorine solution for Well No. 1. Chlorine is 12.5% NaOCL, ANSI/NSF Standard 60 approved and will be applied at a rate of 1.0 mg/l of actual chlorine.
Water Supply Well	Well No. 3, a 200 foot deep well with 170 feet of 8-inch casing and 30 feet of 8-inch, 10 slot screen. The well will be equipped with a 20 Hp submersible pump and motor rated 200 gpm @ 225 feet TDH, set at 160 feet below land surface.
Treatment Facilities	A 5 million gpd water treatment plant located at the north end of Second Avenue. The facility will include 6 low service pumps, 2 rapid mix basins, 4 flocculation/sedimentation basins, 8 dual media filters, 3 million gallon water storage reservoir and 6 high service pumps. Also included are chemical feed pumps and related appurtenances for the addition of alum, fluoride, phosphate and chlorine.

General Project Information – Complete all boxes below.

7. Design engineer's name, engineering firm, address, phone number, and email address:

James E. Redding, PE
ROWE Professional Services Company
PO Box 3748, Flint, MI 48502
(810) 341-7500

8. Indicate who will provide project construction inspection:
☐Organization listed in Box 1.
☒Engineering firm listed in Box 7.
☐Other - name, address, and phone number listed below.

9. Is a basis of design attached?
☒YES ☐NO

If no, briefly explain why a basis of design is not needed.

10. Are sealed and signed engineering plans attached?
☒YES ☐NO

If no, briefly explain why engineering plans are not needed.

11. Are sealed and signed construction specifications attached?
☒YES ☐NO

If specifications are not attached, they need to be on file at DEQ.

12. Were Recommended Standards for Water Works, Suggested Practice for Water Works, AWWA guidelines, and the requirements of Act 399 and its administrative rules followed?
☒YES ☐NO

If no, explain which deviations were made and why.

13. Are all coatings, chemical additives and construction materials ANSI/NSF or other adequate 3rd party approved?
☒YES ☐NO

If no, describe what coatings, additives or materials did not meet the applicable standard and why.

14. Are all water system facilities being installed in the public right-of-way or a dedicated utility easement? (For projects not located in the public right-of-way, utility easements must be shown on the plans.)
☐YES ☒NO

If no, explain how access will be obtained. Improvements are on property under ownership of Genesee County, M-25 ROW, and bottom land easement to be granted by the state.

15. Is the project construction activity within a wetland (as defined by Section 324.30301(d)) of Part 303, 1994 PA 451?
☐YES ☒NO

If yes, a wetland permit must be obtained.

16. Is the project construction activity within a 100-year floodplain (as defined by R 323.1311(e)) of Part 31, 1994 PA 451, administrative rules?
☐YES ☒NO

If yes, a flood plain permit must be obtained.

17. Is the project construction activity within 500 feet of a lake, reservoir, or stream?
☒YES ☐NO

If yes, a Soil and Erosion Control Permit must be obtained or indicate if the owner listed in box 2 of this application is an Authorized Public Agency (Section 10 of Part 91, 1994 PA 451) ☐ Owner is APA.

18. Will the proposed construction activity be part of a project involving the disturbance of five (5) or more acres of land?
☒YES ☐NO
If yes, is this activity regulated by the National Pollutant Discharge Elimination System storm water regulations?
☒YES: NPDES Authorization to discharge storm water from construction activities must be obtained.

☐NO: Describe why activity is not regulated:
Please call 517-241-8993 with questions regarding the applicability of the storm water regulations.

19. Is the project in or adjacent to a site of suspected or known soil or groundwater contamination?
☐YES ☒NO

If yes, attach a copy of a plan acceptable to the DEQ for handling contaminated soils and/or groundwater disturbed during construction. Contact the local DEQ district office for listings of Michigan sites of environmental contamination.

20. IF YOU ARE A CUSTOMER/WHOLESALE/BULK PURCHASER, COMPLETE THE FOLLOWING

1) Name and WSSN of source water supply system (seller) 01800

2) Does the water service contract require water producer/seller to review and approve customer/wholesale/bulk purchaser water system construction plans?
☐YES ☒NO

If yes to #2, the producer/seller approval letter must be attached when submitted to DEQ.

21. **Owner's Certification** The owner of the proposed facilities or the owner's authorized representative shall complete the owner's certification. It is anticipated that the owner will either be a governmental agency (city, village, township, county, etc.) or a private owner (individual, company, association, etc.) of a Type I public water supply.

OWNER'S CERTIFICATION

I, JEFF WRIGHT (print) (name), acting as the AGENT (print) (title/position) for DIVISION OF WATER & WASTE SERVICE (print) (entity owning proposed facilities) certify that this project has been reviewed and approved as detailed by the Plans and Specifications submitted under this application, and is in compliance with the requirements of 1976 PA 399, as amended, and its administrative rules.

Signature* 8-17-12 Date 810-732-1590 Phone

*Original signature only, no photocopies will be accepted.

GENESEE COUNTY DRAIN COMMISSIONER
DIVISION OF WATER & WASTE SERVICES

INTAKE BASIS OF DESIGN
6/29/12

A. Intake General
   1. Single intake pipe
   2. Two cribs spaced approximately 2200' apart, with first crib 3375' off shore
   3. Each crib designed for 60 mgd with future 85 mgd to be considered
   4. Crib 1 location lake bottom elevation = 557
   5. Crib 2 location lake bottom elevation = 551
   6. Lake low water elevation = 576, normal = 578
   7. On-shore structure to be designed to act as both tunneling pit and wet well for pump station. Structure details to be provided at a later date.

B. Intake Cribs
   1. Design: maximum winter flow dictates port size. Worst case maximum winter flow assumed of ½ of future 85 mgd. Limit winter intake velocity to ≤ 0.25 fps and maximum intake velocity (other than winter) to 0.5 fps.

	mgd	gpm	cfs
Design Flow =	85	59,028	131.5
Winter flow rate factor =	1/2		
Assumed max winter flow =	42.5	29,514	65.8
Max. winter velocity =	0.25	fps	
Max. summer velocity =	0.5	fps	
Req'd waterway area =	263.0	sft	
# of ports =	8		
Req'd port area =	32.9	sft	
Square port dim. =	5.734	ft	
Square port dim. =	68.8	in	

   2. Crib Sizing
      a) Crib shall be sized to accommodate ballasting required to submerge / sink the crib and hold it in place against buoyancy. Crib to remain buoyant when ballast ports are empty and sink with ballast ports are filled.
      b) Sized to resist expected currents and design wave height of 30'.
      c) Crib shall be 48' x 48' with base courses 52' x 52'.
   3. Materials
      a) Timber: #1 Structural Douglas Fir, RC, heavy
      b) Fasteners: drift pins and bolting as per ASTM 36
      c) Stone and rip rap: MDOT 916.01

C. Intake Pipe
   1. Design – Pipe capacity designed for 85 mgd. Velocity in 78" intake pipe is 2.80 fps at 60 mgd and 3.97 fps at 85 mgd.
   2. Access – 42" access manholes located approximately every 1500'
   3. Materials – PCCP, RCP or steel pipe

4. Two stop log chambers shall be constructed, one per branch to each crib, so that each crib can be isolated.
5. After the Y split, the pipe reach from Stop Log Chamber 1 to Crib 1 will be 60" pipe in order to achieve balanced flow with both cribs active. At a Hazen Williams C factor of 135 at initial construction, 49.8% of flow will come from Crib 1 and 50.2% of flow will come from Crib 2. The flow split will be 50/50 when the C factor drops to 132. Detailed calculations are available upon request.
6. If Crib 2 were to be out of service, the flow velocity will be 4.73 fps through the segment of 60" pipe to Crib 1 at 60 mgd.

D. Zebra / Quagga Mussel Control
   1. Chemical - chlorine
   2. Piping – dual wall HDPE or CPVC pipe, separate pipe to each crib for redundancy

GENESEE COUNTY, MI -- Decades after talks about **building a water pipeline to Lake Huron (http://www.mlive.com/news/flint/index.ssf/2012/10/ge[illegible]nmissioners_t_9.html)** started, the county is putting its money where its mouth is.

Jeff Wright

The Board of Commissioners unanimously agreed today, Oct. 24, to back up to $35 million in borrowing on first-phase construction of the pipeline -- a massive intake that will stretch 1.5 miles under the floor of the lake.

"It sounds like a lot of money and it is," said county Drain Commissioner Jeff Wright. But "that's how much we spend every 16 months to buy water from our current supplier."

Building the intake is the first visible step in breaking up with that current supplier, the city of Detroit, which has sold treated lake water to the county and city of Flint since the 1960s.

County board Chairman Jamie Curtis said the decision on the initial borrowing "means the pipeline is on its way."

"That opens this whole region up to the blue economy," Curtis said, referring to the potential for job creation by companies that require large volumes of clean, untreated fresh water.

It remains to be seen whether the pipeline will be built in partnership with the city of Flint -- through the Karegnondi Water Authority, through a separate partnership with smaller potential partners including the city of Lapeer and Lapeer and Sanilac counties, or by Genesee County alone.

Wright said he has set a January goal to begin final engineering on the pipeline -- something that can't be done without knowing whether Flint will be a partner in the project.

Flint's decision that will affect every aspect of the preparation, including the size of transmission pipes and pumping stations that will be needed.

The city's participation in the pipeline has been a question mark, partly because a state-appointed emergency manager rather than the mayor or City Council is making financial decision.

Flint emergency financial manager Ed Kurtz has said that he hopes to reach a decision on the future of Flint's drinking water supply within the next several weeks, something that will also require the approval of state Treasurer Andy Dillon.

Flint resident Chris Del Morone said all the communities that stand to benefit from the pipeline should share in the risk of backing the borrowing if revenue from water sales isn't enough to make future debt payments.

"It's not a question of whether somebody is for the pipeline or not," Del Morone said. "Why is it that only Genesee County is ... on the hook for this?"

Several commissioners have said they are weary of waiting for a regional authority to solidify and prepared to build the pipeline alone if necessary.

"We have waited and waited and waited," said board Chairman Jamie Curtis. "We must go forward.

- Detroit
- Flint
- Grand Rapids
- Jackson
- Kalamazoo
- Lansing
- Muskegon
- Saginaw
- All Michigan

"We've crunched the numbers, and we can do it."

The total estimated cost of borrowing for the pipeline is $300 million.

Today's borrowing resolution authorizes Wright to search out the lender that will provide the county with the lowest possible interest rate on its initial borrowing.

The contractor for building the intake portion of the pipeline could be chosen by the close of this year, Wright said, depending on how quickly a U.S. Army Corps of Engineers permit is issued.

Executive Summary

Reliability Plan Purpose & Scope

The purpose of this Reliability Plan is to conduct an evaluation of the City of Flint water distribution system. This study includes analyzing the water distribution system's ability to address the existing and projected future water demands. The *City of Flint Water System Review* performed by the Michigan Department of Environmental Quality (MDEQ) Drinking Water & Radiological Protection Division in 2008, rated the water distribution system as "deficient", citing key improvements being necessary to the water supply including:

- Distribution system improvements
- Transmission system improvements
- Improvements to pumping stations
- Develop the necessary rate structures to operate and maintain the water system and construct the necessary infrastructure to meet the 20-Year Capital Improvement Program.

With this information, the city will be able to identify necessary improvements to the existing water distribution system and plan for additional capacity at water storage facilities and booster pump stations. Furthermore, they will be able to implement and financially plan for the proposed water infrastructure improvements in the future.

Reliability Study Major Tasks Completed

- City of Flint water system model ported to GIS-based modeling software and model updated to reflect current demands and conditions.
- City of Flint General Plan updated to reflect existing conditions and show all valves and hydrants.
- Genesee County demands added to model.
- Annual Average Day (AAD), Maximum Day (MD), and Peak Hour (PH) scenarios developed.
- Six-Year Capital Improvement Program
- Valve and hydrant assessment
- Calibration of Model
- Calculation of unaccounted for water
- 20-year operational alternatives evaluated
- 20-year demands evaluated and modeled for AAD, MD, PH
- 20-Year Capital Improvement Program
- Water System Asset Evaluation
- Water System Recommendations
- Preliminary Asset Management Plan

Recommendations

The following lists the recommendations of this study (in order of priority):

A. Water System Efficiency

The city's average water system efficiency for the last five years is 63% and this equates to lost revenue in the range of $1.5 million to $2.0 million dollars per year. A program to improve the water system efficiency should be put in place. The key tasks for this program are outlined in Section 4.

B. Water System Storage and Pumping Capacity

The water system has sufficient storage and pumping capacity, however some of the pumping facilities are in need of rehabilitation. The city has submitted a DWRF Project Plan to the Michigan Department of Natural Resources and Environment (DNRE) which includes upgrades to Torrey Road and Cedar Street. These improvements should be completed as funds are available. The pumping and storage capacity of the system exceeds the design requirements for the system, and should be evaluated going forward as the city shifts its long term operating strategy from the Detroit Water & Sewerage Department (DWSD) System to either the Flint River or Karegnondi.

C. Capital Improvement Program

The Water Reliability Study outlines a number of improvements in the short term and over the 20-year study period. The 24" transmission main is the first priority and is eligible for DWRF funding and should be constructed as funds become available. The second priority should be the upgrade and rehabilitation of P.S. 4 on the plant grounds. This station will be key in the future operating scheme of the city system. The Capital Improvements outlined in the report should be evaluated and prioritized on a regular basis as the city moves forward with decisions regarding the long range operation of the system. Table 1 on Page 4 shows the Six-Year CIP projects and the related costs and the map in Appendix 1 shows the locations of the Six-Year CIP Improvements.

D. Valve Replacement Program

The city system includes a variety of valves, and many of these valves are in excess of 50 years old and are in need of replacement. The Water Reliability Study outlines a valve replacement program that would replace these valves over time and at reasonable cost to the system.

E. Hydrant Replacement Program

Similar to the valves, many of the hydrants in the system are in excess of fifty years old and are in need of replacement. The Reliability Study outlines a program to replace the hydrants over time and at a reasonable cost to the system.

F. Water System Automation

Supervisory Control and Data Acquisition (SCADA) systems allow water utilities to more efficiently operate and maintain their system. The city has a moderate SCADA system that is in need of

upgrading and expanding. The review of the SCADA system was not in the scope of this study, but it should be evaluated and upgraded.

G. GIS Based Asset Management

The city has established a GIS Department that is working on inventorying the water and sewer assets of the city. Some of this information was used in the preparation of this report. Given the size and age of the city's water and sewer assets, it would be prudent to incorporate a GIS-based asset management program. There are several packages on the market that can be customized to fit the city's needs.

Table 1: 6-Year Capital Improvement Table

Project Number	Capital Improvement Program	Design Status	Construction Status	2010 Construction Costs	Contingencies, Engineering, Management and Legal (CEM&L @ 47%)	Total CIP Project Cost
	Major Booster Station Improvement Projects					
Project 1	Torrey Road Booster Upgrades (In-house)	Design Complete	Construct 2010	$300,000	$141,000	$441,000
Project 2	Water Pumping Station 3 Electrical and Controls Upgrade	Design in Progress	Construct 2010	$900,000	$423,000	$1,323,000
	Sub Total			**$1,200,000**	**$564,000**	**$1,764,000**
Project 3	**Major Transmission System Improvement Projects**					
Project 4	28,000 LFT of 24" & 30" watermain; WTP to Dupont; South to University	Design Complete	Construct 2011	$10,000,000	$4,700,000	$14,700,000
Project 5	Water Meter Replacement Program 3,000 meters/year		2010-2015	$1,000,000		$5,000,000
Project 6	15,500 LFT of 12" & 24" watermain; Saginaw Street, Flint River to Pierson Road	2010	2012	$3,800,000	$1,786,000	$5,586,000
Project 7	16,100 LFT of 16" watermain; Atherton Road, Van Slyke to Dort	2010	2013	$4,000,000	$1,880,000	$5,880,000
	Sub Total			**$18,800,000**	**$8,366,000**	**$31,166,000**
	Minor Transmission System Improvement Projects					
Project 8	500 LFT of 6" watermain; Hamilton Avenue, Mason Street to MLK Boulevard.	2010	2011	$50,000	$23,500	$73,500
Project 9	1,650, LFT of 6" watermain; Sonny Avenue, Dupont to Lawndale	2010	2011	$165,000	$77,550	$242,550
Project 10	1500 LFT of 6" watermain; Walton Street, Clairmont to Augusta	2010	2012	$150,000	$70,500	$220,500
Project 11	1500 LFT of 6" watermain; East Boulevard, Farmers Market to Park	2011	2013	$150,000	$70,500	$220,500
Project 12	325 LFT of 6" watermain; Alexander Street, Taylor to Rankin	2011	2014	$32,500	$15,275	$47,775

Section 2 - Introduction

2.0 Background

The City of Flint currently provides water service to a population of approximately 118,000 through an extensive network of transmission and distribution mains. Many of these mains are aging and are in need of replacement. The city also operates several booster pumping stations and storage facilities to boost pressures and enhance service. The *City of Flint Water System Review* performed by the Michigan Department of Environmental Quality, Drinking Water & Radiological Protection Division in 2008, rated the water distribution system as "deficient", citing key improvements being necessary to the water supply including:

- Distribution system improvements
- Transmission system improvements
- Improvements to pumping stations
- Development of an Asset Management System

The review also states that much of the piping within the City of Flint is more than 70 years old and is in serious need of replacement. The City of Flint Water Service Center, which operates and maintains the water system, spends a significant amount of time repairing mains that are in poor condition. Each winter, a large number of watermain breaks occur due to the aging condition of the watermains. These breaks result in interruptions in water service and potential public health risks to city customers.

In response to this deficiency rating, the city retained ROWE Professional Services Company to develop a Water System Reliability Study to correct these deficiencies.

Before beginning the Water Reliability Study process, ROWE Professional Services Company met with City of Flint officials and Michigan DNRE staff to determine the goals of the study. These discussions produced a three-phase approach to addressing the issues raised by the DNRE. This study completes the first two phases; Phase 3 includes the treatment plant and will be analyzed in a future study.

A. Phase 1 – Model Update and Short Term CIP

Key tasks include:

- Update the city's water model including demand allocations, pumping and storage facilities, piping changes, and other associated infrastructure
- Update the city's General Water Plan
- Evaluate existing conditions and develop a short-term (6-year) Capital Improvement Plan
- Update the Contingency Plan
- Calibrate the city water model
- Analyze valve and hydrant deficiencies

B. Phase 2 – Distribution System Asset Management and 20-Year Capital Improvement Plan

Key tasks include:

- Develop modeling scenarios for 20-year water system plan
- Develop 20-year plan for the water system
- Prepare cost opinions for 20-year plan
- Analyze rate structure to support 20-year plan
- Develop an asset management plan
- Inventory water distribution system assets

2.1 Existing Conditions

A. Source Facilities

The City of Flint purchases treated water from the City of Detroit through the DWSD. The treated water is supplied to Flint via a 72-inch transmission main. This transmission main also provides water service to Genesee County and several other communities between Flint and Detroit. The flow to the City of Flint is metered to provide accurate water use records.

The city also maintains a water treatment plant as a backup supply in the event that the City of Detroit water supply is interrupted. Work to upgrade the City of Flint Water Treatment Plant (WTP) began several years ago and is progressing to completion. A number of test runs were initiated in 2006, 2007, and 2008. Additional test runs are planned for the future. The majority of the improvements at the plant have been implemented as a result. The plant is generally ready for use in a standby capacity, in the event that service from the City of Detroit water supply is interrupted. Long-term plans include provisions for expanding the capacity of the plant and implementing a softening system.

B. Water Treatment

The water purchased from the DWSD is already treated prior to reaching the City of Flint system; typically, no further treatment is required. The City of Flint also owns and operates a water treatment plant located at 4500 North Dort Highway, which serves as a backup supply in the event of a major service disruption from the DWSD water supply. The source for the City of Flint water treatment plant is the Flint River. The city has made significant improvements to the plant over the past five years and operates the water treatment plant on a quarterly basis to ensure proper operation of the plant. According to the contract with the DWSD, this water is isolated from the DWSD supply to prevent water from the two different supplies from mixing.

While the treatment plant is considered a viable backup water supply for the system, the plant is not currently operating. There are additional issues that will require a significant amount of capital investment in the future. The City of Flint estimates that the upgrades to the water treatment plant will cost approximately $25,000,000.

C. Evaluation of Storage and Pumping Facilities

The City of Flint owns and operates several water storage facilities and pumping stations. The *City of Flint Water System Review*, prepared by the MDEQ, includes a detailed review of these facilities. This review states that adequate storage and pumping facilities are currently in place; however, most of the systems are nearing their useful life and are in need of repair or replacement. A brief overview of each facility follows.

1. Dort Reservoir and Pumping Station No. 4 (P.S. No. 4)

   The Dort Reservoir is located at the City of Flint WTP and is a 20-million gallon (MG) ground storage facility. This facility was constructed in 1966 and is used primarily for emergency water storage and for use during peak water demand periods.

   Pumping Station No. 4 is equipped with three 20 mgd turbine pumps, one 25 mgd turbine pump, and one 6 mgd turbine pump. Pumps 7, 8 and 9 were installed in 1994 and Pumps 1 and 2 were installed in 1949. Pumps 1 and 2 are both considered inoperable and there are no plans to replace or repair the inoperable pumps at this time. The total pumping capacity of this station is 46 mgd, with a firm pumping capacity of 26 mgd. In 1994, the pumping station was rehabilitated with two new 20 mgd pumps and one 6 mgd pump to induce turn-over of the Dort Reservoir. This pumping station is primarily used to provide a supply from the 20 MG Dort Reservoir during emergency situations and peak demand events.

2. WTP Elevated Tank

   A 2.0 MG elevated water storage tank is located at the WTP. This tank was constructed in 1952 and is used primarily for emergency water storage and as a pressure buffer. The elevated tank fills and drains as system demands and pressures dictate. The tank was inspected and repainted in 2009.

3. WTP Ground Storage Facility

   A 3.0 MG ground storage tank is also located at the WTP complex. This storage tank was constructed in 1954 and is used primarily as an emergency water supply and pumping source during peak demand events.

4. Cedar Street Reservoir and Pumping Station (P.S. No. 3)

   The Cedar Street Reservoir is a 20 MG ground storage facility located between I-69 and Swartz Creek, off of Cedar Street. This facility was constructed in 1948 and is primarily used as an emergency water supply and pumping source during peak demand events. The pumping station electrical controls have not been updated since the original construction. The station requires significant upgrades to bring the station up to current automatic operation standards.

The pumping station located at the Cedar Street facility is equipped with three single-stage horizontal centrifugal pumps rated at 12 mgd, 9 mgd, and 9 mgd, respectively. These pumps were installed in 1948 and are primarily used to supply water from the Cedar Street reservoir during emergency events and peak demand periods. This pumping facility has a total pumping capacity of 30 mgd and a firm pump capacity of 18 mgd.

Pump operation and filling of the reservoir can be controlled from the WTP or manually at the pumping station. Typically, the reservoir is refilled at night during low demand periods. The pumping station is equipped with chlorination facilities to provide additional chlorine residual as needed.

5. West Side Reservoir and Pumping Station (P.S. No. 5)

The West Side Reservoir is a 12 MG ground storage facility located near Mackin Road and Jean Avenue. This facility was constructed in 1970 and is primarily used as an emergency water supply and a pumping source during peak demand events.

The West Side Pumping Station is equipped with 2 three-stage turbine pumps and 2 two-stage turbine pumps, all installed in 1970. Pumps 1 and 2 have a capacity of 8 mgd each, and Pumps 3 and 4 have a capacity of 4 mgd each. The total pumping capacity of P.S. No. 5 is 24 mgd with a firm pump capacity of 16 mgd.

Pump operation and filling of the reservoir can be controlled from the WTP or manually at the pumping station. Typically, the reservoir is refilled at night during low demand periods. The pumping station is equipped with chlorination facilities to provide additional chlorine residual as needed.

It is recommended that the existing swing check valves on two of the pumps at this station be replaced to allow for proper operations of the station, and to eliminate water hammer caused by the spring check valves upon start up and shut down of the pumps. This work was budgeted for 2006 and 2007, but never implemented. The city is currently working to implement these upgrades in 2012.

6. Torrey Road Pumping Station

The Torrey Road Pumping Station is equipped with two centrifugal pumps rated at 2.8 mgd and 4 mgd, respectively. Both pumps were installed in 1954. The station has a total pump capacity of 6.8 mgd and a firm pump capacity of 2.8 mgd. The primary function of this station is as an in-line booster pumping station to provide increased pressures to the southwest portion of the city. This pumping station takes suction from the 24" transmission main along Hammerburg Road and discharges to the 18" transmission main supplying the southwest pressure district. There is no standby power provided to this pumping station.

The City of Flint has made plans to replace the existing pumps and piping in the station. The existing pumps have exceeded their useful life and the piping and valves are in poor condition. The station is scheduled for upgraded pumps and interior piping in 2012. Permit applications were submitted to the DNRE in April 2010.

D. Condition of Service Lines

Service lines appear to be in adequate condition, with typical repairs made by city staff, depending on the age of the existing watermain and water services connected to it. The city does experience problems with a number of existing valves. The long-term needs for the system include replacement of the existing valves over the next 20 years. The total estimated cost to replace the valves is approximately $2,000,000.

E. Type of Conveyance System

The conveyance system of the City of Flint consists of water distribution and transmission main ranging in size from 4" to 72" in diameter. Many of these mains exceed 70 years old, and the majority are constructed of cast iron or ductile iron pipe up to 24" in diameter. Transmission mains larger than 24" are primarily constructed of steel piping.

The majority of the city's system has adequate transmission piping to convey sufficient flows and pressure for fire protection. However, the distribution and transmission systems are old and in serious need of replacement. Every year, a large number of watermain breaks occur within the city. These breaks, which are repaired by city staff, result in serious water service disruptions and potential water quality problems to customers of the City of Flint. The Six-Year Capital Improvement Program (CIP) in Table 1 is intended to remedy the most pressing of these infrastructure problems and the 20-Year CIP in this study will take a long term look at system-wide problems and solutions. Recent improvements to the distribution system are shown in Appendix 2.

F. Appurtenances

The City of Flint system appurtenances, similar to the conveyance system, are in general over 50 years old and in constant need of repair or replacement.

1. Valves

   The City of Flint distribution system currently has 3,931 gate valves and 3,327 gate well valves for total valve count of 7,258 valves to be operated and maintained. A breakdown of the valves by size is shown in Table 2 below.

Table 2: Valves by Size

Valve Size	Valve Count
72"	20
24" and >	661
16 - 20	737
12	1398
<12	4462

The development of an asset management plan for the valve system would include a process to move from reactionary valve maintenance to planned preventative maintenance and replacement. Given the size and age of the city system, this will take some time to transition and the following is a general outline of a plan to accomplish this over a 20-year period while addressing the critical valves within two years. In general, the asset management plan for the operation and maintenance of the valve system has been divided into three categories: critical; subcritical; and normal.

Critical valves are 16" and larger that are on the primary transmission mains around the city, and in the event of a break in a major transmission main, valve failure, or multiple valve failures, could result in shutting down a significant portion of the city. A preliminary evaluation indicates that there are 1,398 critical valves in the system and these valves should receive primary attention. Primary attention would consist of operating the valves on a rotating two-year basis and making all repairs and replacements that are necessary. Approximately 700 critical valves would be operated and maintained each year.

Subcritical valves are the 12" valves on minor transmission mains and the failure of one or more of these valves could result in shutting down a residential area. There are 1,398 subcritical valves in the system. These valves should receive secondary attention which would consist of a 5-year plan for operation and maintenance. This would require that approximately 280 valves be operated and maintained each year.

Normal valves are any valve smaller than 12" and the failure of one or more of these valves would shut down a small residential area. There are 4,462 of these valves in the system and these valves should receive operation and maintenance attention on a 10-year rotating basis. Approximately 450 valves would require attention each year.

The total valve operation and maintenance program would require that approximately 1,430 valves receive routine maintenance each year, in addition to any emergency repair and replacement that is required during the course of a year. Appendix 3 includes a map of the water system valves.

2. Hydrants

The City of Flint has 3,605 hydrants in the water system and as with the watermains and valves; many of these hydrants are in excess of 50 years old. In the spring of 2010, the city purchased 80 hydrants to begin replacing old hydrants while the Reliability Study was completed.

Similar to the asset management approach to the valve maintenance, the plan for hydrants would include a transition from reactive maintenance to planned maintenance and replacement. Here the goal would be to analyze the hydrant age in the system and begin to change out hydrants in excess of 50 years old, and then over a period of twenty years create a system where hydrant age did not exceed 25 years. Appendix 4 includes a map of the water system hydrants

G. Method of Residuals Handling

The WTP is a back-up facility and does not currently generate significant residuals. If the WTP becomes the primary water source for the city, a residuals management plan will need to be submitted to the MDEQ.

H. Design Capacity of the System

The design capacity of the waterworks system, in the form of the maximum day demand, is 36.0 mgd. The total source capacity from the DWSD exceeds 70 mgd, with a firm source capacity of 36 mgd.

The City of Flint has completed the WTP rehabilitation project, which was partially funded through the DWRF program. The city has already conducted several trial runs and is expected to complete the project in the near future. The improvements result in a firm capacity of 36 mgd.

I. Operation and Maintenance of the System

The City of Flint operates the system manually, using trained personnel with the experience and knowledge to assure proper and adequate control of the system. City personnel estimate the daily water demand anticipated to service the City of Flint and surrounding Genesee County communities and communicate such needs to personnel at the DWSD, who ensure delivery. City staff usually communicates with DWSD staff twice daily.

Water is supplied from the DWSD at an approximate pressure of 103 psi. Water demands of Genesee County communities are taken off the distribution system between the location of the DWSD water supply meter and Control Station 2 (CS 2) at the City of Flint WTP. CS 2 has a pressure reducing valve which regulates and lowers the supply pressure from 103 psi to approximately 75 psi.

If the supply pressure from the DWSD is greater than 105 psi, the valve to the Dort Reservoir at Control Station 3 (CS 3) is opened. The valve at CS 3 is also operated when the water level in the elevated tank is more than 33 feet. The Dort Reservoir is kept at a 16 foot level to have available volume for water demand fluctuations.

The Dort Reservoir is connected to Clear Well No. 3 through a valve at Control Station 5 (CS 5). The 6 MG pump located in P.S. No. 4 is used to turn over the water stored at the Dort Reservoir. The other pumps are used, as necessary, to increase distribution system low pressures due to fire flow, main breaks, and high demands.

The elevated tank fills and empties based on system pressure. If the elevated tank level drops below 20 feet during the hours of 7:00 a.m. and 3:00 p.m., P.S. No. 3 at the Cedar Street Reservoir or P.S. No. 5 at West Side are placed on-line to supply additional water to the system. Typically only one of the two stations is used at a time, and station use is alternated in order to ensure proper operation of the system.

The Cedar Street and West Side Reservoirs are filled during the night between the hours of 11:00 p.m. and 7:00 a.m., after the elevated tank is full. The West Side Reservoir is filled first; when its level is 16 feet, the filling of Cedar Street Reservoir begins.

Pump Stations 3, 4, and 5 are controlled remotely from the Water Plant Facility. The filling operation of the reservoirs is based on opening the fill valves remotely. The fill rates are controlled by opening the valve a certain percentage.

The Torrey Road Booster Pumping Station is controlled utilizing a pressure sensing station at Brown Street and Bradley Avenue (B&B). The booster pumping station has two pumps. Pumps 1 and 2 are normally operated to maintain pressure at B&B between 40 & 50 psi. This pump station does not have a secondary power source (auxiliary power) in case of power interruption.

2.2 Water Master Plan References

Several studies, reports, maps and publications were used as reference material in completing the City of Flint Water Reliability Study, including the following:

1. 2009 City of Flint DWRF Plan
2. *Modeling, Analysis, and Design of Water Distribution System*, Lee Cesario, American Water Works Association, 1995
3. *Recommended Standards for Water, Great Lakes Upper Mississippi River, Board of State Public Health and Environmental Managers (Ten State Standards)*, 2003
4. City of Flint website
5. U.S. Census Bureau surveys

2.3 Abbreviations

AADD – Annual Average Day Demand
AWWA - American Water Works Association
DIP - Ductile Iron Pipe
DPW - Department of Public Works
DWSD - Detroit Water & Sewerage Department
FWS – Flint Water System
GCDC - Genesee County Drain Commissioner
GCDC-WWS - Genesee County Drain Commissioner, Division of Water & Waste Services
gpd - gallons per day
gpcd - gallons per capita per day
MGD - Million Gallons per Day
gpm - gallons per minute
HGL - Hydraulic Grade Line
Hp - Horsepower
ISO - Insurance Services Office
MG - Million Gallons
MDD - Maximum Day Demand
MDEQ - Michigan Department of Environmental Quality
DNRE – Department of Natural Resources and Environment
MDOT - Michigan Department of Transportation
O&M - Operation and Maintenance
ROW - Right-of-Way
ROWE – ROWE Professional Services Company
PHD - Peak Hour Demand
psi - pounds per square inch
REU - Residential Equivalent Unit
TDH - Total Dynamic Head
USEPA - United Stated Environmental Protection Agency
USGS - United States Geological Survey
VFD - Variable Frequency Drive
WTP - Water Treatment Plant

2.4 Staffing

Operation of the City of Flint water system is provided by the WTP staff and maintenance of the distribution system is provided by the Water Service Center. The organizational charts for the two entities are included in Appendix 5.

The Water Treatment Center currently has 28 budgeted positions with five vacancies. The city is currently interviewing for three of the vacant positions and will evaluate staffing needs after these three positions are filled. Due to economic conditions in the city, it is unknown whether the remaining vacancies will be filled.

The Water Service Center has 48 full-time equivalent positions with 5 vacancies. Due to economic conditions, there are no current plans to fill the vacancies. In early 2010, crew levels were reduced and overtime was eliminated curtailing the Water Service Center's ability to maintain the system.

2.5 Existing Capital Improvement Plan

In 2009, ROWE prepared a DWRF Project Plan for the city outlining a number of projects, including replacement of the Torrey Road Booster Station and the construction of 28,000 feet of 24" watermain. Due to economic conditions these projects have not been constructed. A revised 6-Year City of Flint CIP is shown in Table 1 in the Executive Summary. The city is currently moving forward with the replacement of key equipment at the Torrey Road Station and electrical and control improvements at the Cedar Street Station. The city is currently seeking funding for the 24" watermain and hopes to begin construction in 2012.

2.6 Existing and Proposed Water Service Area

The City of Flint is the service area for the purpose of the Reliability Study. However, the city provides water to Genesee County from several metered connection points along the city's 72" feed from the DWSD (see general plan). The city does not operate or maintain the county system.

The City of Flint, along with Genesee County, Lapeer County, and the City of Lapeer, formed the Karegnondi Water Authority for the purpose of exploring the possibility of developing a Lake Huron water intake and providing raw water to the member communities. The member communities would then treat the raw water at plants located within their jurisdiction.

The City of Flint has also entered into discussions with Genesee County to provide emergency backup water supply to a portion of the county system. At this writing, the volume under discussion was 8 MGD to be delivered at a connection point to be determined, on the north side of the City of Flint water system. This is discussed further in Section 3.6.

2.7 General Plan

The general plan of a water system is essentially a map of the system showing watermains, valves, hydrants, and major pumping and storage facilities of the system. The general plan can also include such items as pressure districts; however, the Flint Water System (FWS) operates as one pressure district. The general plan has been updated as part of this report and is included in Appendix 6. Areas that were updated are highlighted and labeled.

2.8 Cross-Connection Program

The city operates a cross-connection plan through the wastewater plant. The cross connection program is in compliance and a copy of the program is on file at the city.

2.9 Water Shortage Response Plan

There are several potential situations that could result in a water shortage in the City of Flint. In each case, the city has sufficient infrastructure, equipment, and redundancy to resolve any water shortage situation that may arise. In each case, a press release outlining the nature of the water shortage and a request to limit water usage would be issued by the city. The following are representative of these potential situations:

A. Loss of Service from the DWSD

In the event that the city loses water service from the DWSD, the city would run off the 57 MG of existing storage, while implementing its EOS by putting the back-up water plant in service to feed the system, until such time as water service from the DWSD is restored.

B. Loss of Elevated Tower

The city currently has one elevated tower located on the treatment plant grounds. In a case where the elevated tower was out of service for repairs or painting, the system would run off the DWSD pressure with peak flows supplied by the West Side Station, Cedar Street Station or Torrey Road Booster Station. DWSD pressure would refill the storage at Cedar and West Side each night.

C. Loss of Pumping Facility

The City of Flint water system is supplied by DWSD water pressure. The city has three pumping facilities in addition to P.S. No. 4 at the plant. West Side Pumping and Storage Facility, and Cedar Street Pumping and Storage Facility, are alternated each day to supply peak flows to the system. In the event that either of the stations were out of service, the other could supply all the needs of the city. In the event that both stations were out of service, the system could run off the DWSD pressures. The Torrey Road Booster Station supplies peak flows to the Hospital Hill area. In the event that Torrey Road Booster Station was out of service, the Cedar Street Station could be used to supply peak flows to the hospital area.

D. Watermain Break on Major Transmission Main

The city has a well-designed system with significant looping of major supply lines. Extensive modeling was done with various sections of the key transmission mains out of service and in all cases the impacts were minimal. This analysis assumes that system valves will operate as intended.

2.10 Contingency Plan

The contingency plan outlines the emergency measures that can be taken in the event of a major infrastructure failure or local disaster. The plan includes emergency notification procedures, emergency contact numbers for city employees, contractors, neighboring municipalities, and other information related to managing water system emergencies. The contingency plan was updated in 2010 and a copy is on file at the city.

2.11 Historical Water Use

Water use is determined primarily by the total of residential, commercial and industrial use. Historical purchases and sales records can be very useful in determining future system improvements. Meter records indicate the amount of water supplied to the City of Flint. City records show the metered sales for residential, commercial and industrial customers. Table 3 below summarizes the city's historical water use, including Genesee County, for the past eight years. Table 4 shows the city's usage during the same period.

Table 3: City of Flint Flows from the DWSD (MG)

Year	Flows
2004	30.76
2005	31.80

2.12 Water Distribution System Master Metering – Genesee County

Genesee County is the city's largest customer and takes water off the 72" pipeline at a number of locations, and has the ability to take water from the Flint distribution system. The following Table shows the Genesee County meter locations and AADD for each meter location.

Table 5: Water Distribution System Master Metering – Genesee County

Meter Location	Meter Size	2011 AADD (MGD)
West Carpenter	6"	Inactive

2.13 Unaccounted for Water Use

The difference between the quantity of water supplied to the City of Flint and the quantity sold to customers is referred to as "unaccounted for" water. Water in a public system can be unaccounted for due to a number of reasons. Water withdrawn from a fire hydrant, whether it is to fight a fire or flush a water main, is un-metered and therefore "unaccounted for". Leaks and watermain breaks, faulty or inaccurate meters, unauthorized connections and un-metered municipal water use also contribute to "unaccounted for" water.

Water system efficiency analysis indicates that the City of Flint system averages 63 percent over the last five years. This indicates that the city has significant leaks, inaccurate meters and/or illegal connections to the system. A high priority should be placed on implementing a program to reduce the "unaccounted for" water. The program should include: testing high volume meters, leak detection analysis, residential meter replacement, billing system review, and fire flow estimates.

Table 6 and 7 below show the historical "unaccounted for" water.

Table 6: FWS and GCDC-WWS Combined "Unaccounted for" Water

Year	[illegible]	[illegible]	[illegible]
2004	15,008,384	12,599,895	83.95%

2.14 Demographics

A. Population

Flint lost almost 18,000 people between the 2005 mid-decade census and the 2010 census. Given the current economic situation, this trend is anticipated to continue over the next twenty years. See Appendix 7 for full Genesee County population data.

Table 8: Population Figures

Year	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
2005	120,283	41,026	1,500	42,526			
2010	102,400	35,052	1,686	36,738	7,851	18,319	23,552

2030	94,000	32,176	1,548	33,724	7,207	16,817	21,620

Population projections from Regional Planning Agencies for the 2010 Census are not available as of this writing.

Genesee County, which accounts for approximately 57% of the water usage, is the largest purchaser of water from the City of Flint. For the purpose of the table below, the water usage by Genesee County has been removed from the calculations. The following table lists the major water users among the commercial and industrial operations in the City of Flint.

Table 9: Major Water Users

2.15 Land Use

The zoning map shows the city remaining relatively constant over the next five years, as there is little pressure for growth into vacant, open or wooded areas. It is difficult to predict land use over the next 20 years, except to say that most of the industrial urban cities along the I-75 corridor in Michigan have experienced very little growth pressure over the last 10 years and reported a loss in population with the 2010 census. Both of these are true for the City of Flint, and population loss has increased since the 2010 census. It is likely that this trend will continue in the near future. The map in Appendix 8 shows the general location of existing land uses in the area.

2.16 Modeling Conditions & Scenarios

For purposes of this study, four conditions were analyzed. These conditions include the following:

A. Existing System and Future System

The existing water distribution system was analyzed with the current demands from the existing developments to identify potential capacity problems within the existing water infrastructure. The existing demands were developed from City of Flint billing records, Genesee County meter pit data, and DWSD data.

1. Annual Average Day Demands (ADD)
2. Maximum Day Demand (MDD)
3. Peak Hour Demand (PHD)
4. Fire Flow Demands (FFD)

Section 3 - Water Demands

System demands were developed from City of Flint billing records and water plant records. Demands for Genesee County meter pits were developed from Genesee County data. Residential demands were spread evenly across the system. Commercial demands were evaluated individually and attributed to the nearest node in the model. Genesee County demands were input at master meter pit locations.

3.0 Annual Average Day Demand (AADD)

The AADD is the total annual water use divided by 365 days/year. In the case of the City of Flint, the AADD's were developed using City of Flint billing records, water plant information, master meter readings, commercial meter analysis and the modeling process. A summary of that data is provided in Table 10 below. Annual Average Day Demand contours are shown in Appendix 9.

Table 10: City of Flint Annual Average Day Demands

	Number of Units	Water Usage				
Residential	32,604	162,937	1,955,248	123	4,006,919	2,783
Commercial	1,768	292,701	3,512,417	4,128	7,198,049	4,999
City Totals	38,184	475,788	5,709,456	4,404	11,700,474	7,781
GCDC Meter Pits	10	510,133	6,121,590	1,254,506	12,545,067	8,712
All	72,566	1,441,559	17,298,711	492	35,450,509	24,275
2011 Data						

3.1 Maximum Day Demands (MDD)

Maximum day demand (MDD) is the highest daily usage that occurs during the course of a year. Public water systems typically experience a variety of demands generated by the community. Water usage can vary from season to season, day to day, and even hour to hour. Water usage is usually higher during certain times of the week and certain times of the day. Water usage is also typically higher in summer months and lower during the winter months. A water system must be able to meet the wide range of demands expected to occur.

A public water distribution system should have adequate water supply to meet the MDD. Generally, system storage and system pumping facilities should be sized to buffer the difference between AADD and MDD. The MDD is the greatest amount of water used over a 24-hour period. The observed MDD from the city in the last five years is 26.38 MGD and occurred in 2007. Typically MDD are 2-3 times average day demands. The City of Flint's MDD is approximately 1.5-2.0 times average day and this would be typical of an older system with minimal lawn sprinkling demand.

Maximum day pressure contours are shown in Appendix 10. There is a small area that the model projects Maximum day pressure at 35 psi. It is recommended that the city perform some pressure tests in this area to determine the whether the field conditions mimic the model conditions.

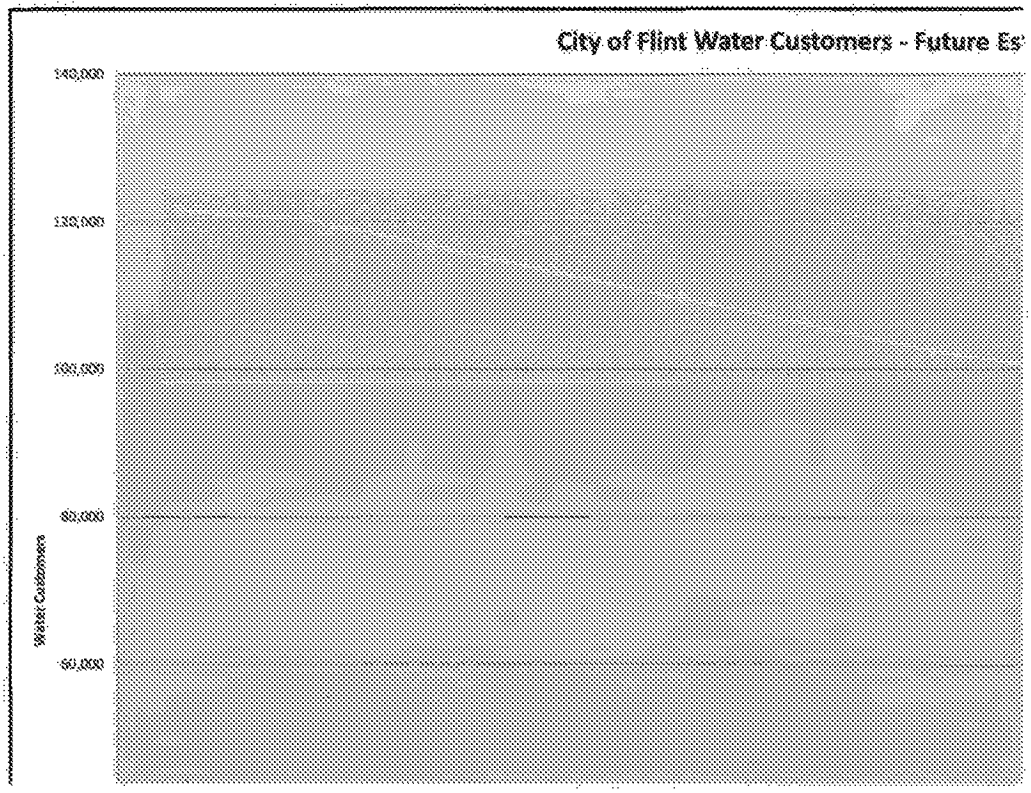
3.2 Peak Hour Demands (PHD)

The PHD is the greatest amount of water used during any 60-minute period of time. Generally, storage should be available to provide the difference between the PHD and MDD. The water distribution system must be able to deliver the PHD. Peak hour demands are not available from the city and are estimated to be three times the average hour.

3.3 Future Demands

Genesee County Metropolitan Alliance and Genesee County Planning Commission Table in Appendix 7 indicates that the population in the City of Flint will continue to shrink through the period of the study 2010 through 2030. Figures 1 and 2 below illustrate the declining population, customers, and declining water use projections for the city.

Figure 1: City of Flint Water Customers - Future Estimates



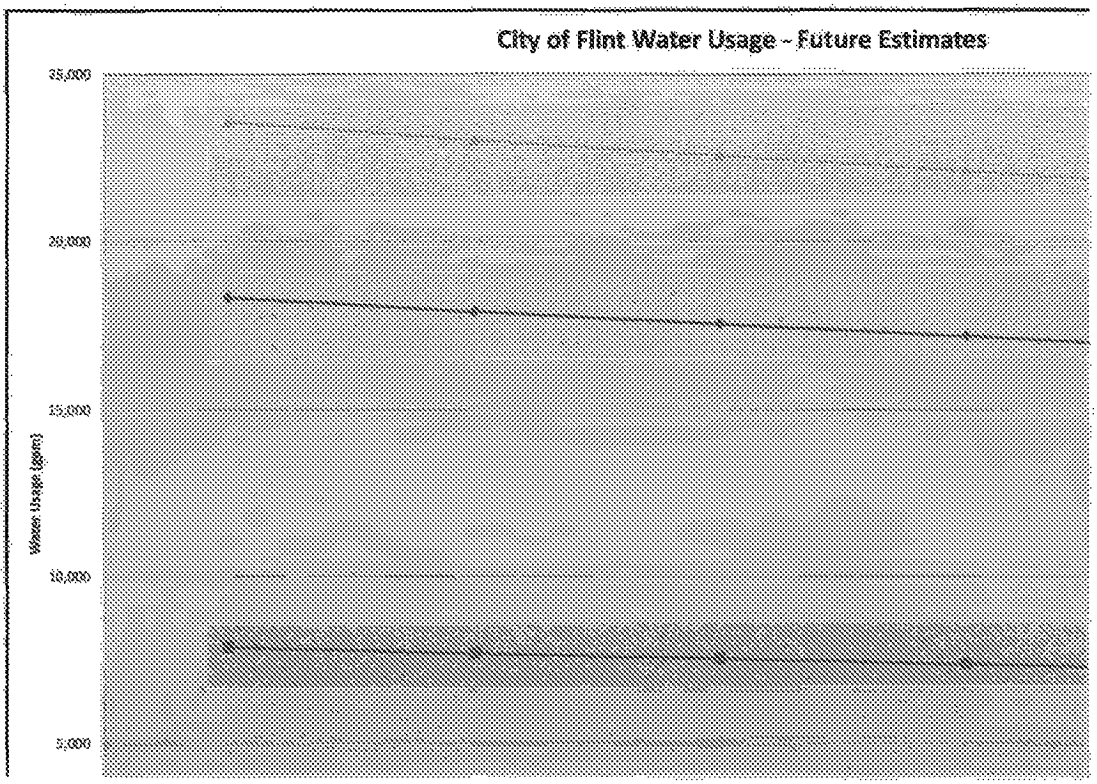


Figure 2: City of Flint Water Usage - Future Estimates

3.4 Fire Flow Demands (FFD)

In the event of a fire, it is desirable that a public water distribution system be capable of meeting certain flow and pressure guidelines established by the AWWA and ISO for public water systems. The actual recommendations for fire protection vary depending on factors such as building use, construction materials, fire suppression regulations, and proximity to hydrants. The following fire flow criteria were developed using ISO and AWWA guidelines. Areas of the city that have 4" pipe will not meet these standards in some cases, and the following are goals to be taken into consideration when planning and designing upgrades for the FWS.

A. Residential Fire

In the event of a residential fire, a water demand of 1,000 gpm should be available for firefighting for a period of four hours. The system should maintain a minimum pressure of 20 psi throughout the remainder of the water distribution system during the time the fire is being fought. The areas of the city that are unable to meet the fire flow goal are located where 4" watermains are present. The 4" watermain replacement plan will remedy the fire flow deficiencies in these areas.

B. Commercial or Industrial Fire

In the event of a school, commercial, or industrial building fire, a water demand of 1,500 gpm should be available for firefighting for a period of four hours. The water distribution system should maintain a minimum pressure of 20 psi throughout the remainder of the water distribution system during the

time the fire is being fought. A representative number of locations were modeled and in cases where the watermain was at least 8", the system met the above criteria. ISO recommendations for commercial and industrial facilities vary significantly and can be as high as 5,000 gpm. Interior sprinkling systems for these types of facilities are highly desirable.

Section 4 - 20-Year Water Supply, Distribution and Storage

4.0 Water Supply Planning Criteria

The following were used as planning standards for this study:

1. System pressures not lower than 20 psi and not higher than 100 psi
2. Normal operating pressures between 40 psi and 75 psi
3. System storage requirements of 2 times Average Day Demands, plus storage for fire flows
4. Firm pumping capacity to meet Maximum Day Demands
5. Future fire flow capability of 1,000 for residential and 1,500 for commercial

4.1 Water Supply

The city faces three potential scenarios for water supply in the near future. 1) Remain with the City of Detroit system; 2) complete the upgrades to the city water plant and use the Flint River as the water source; or 3) participate in the Karegnondi Water Authority, which will use water from a new Lake Huron intake near Sanilac, Michigan and supply raw water to several communities including Flint and Genesee County. The city has determined that the long-range plan for water supply will either be scenario 2 or 3 above, which will require the operation of the water plant on a full-time basis. The reliability study will analyze the needs of the distribution system including P.S. No. 4, the high service pumping facility located on the water plant grounds.

4.2 Water Storage Facilities

There are several ways to evaluate water system storage. One commonly accepted method is that the system should have two times average day flow, plus fire flow storage. The city's current average day flow is 14.04 MGD, therefore the calculated system storage requirement would be 28.1 MG plus fire flow storage. Assuming simultaneous residential and industrial fires at 1,000 gpm and 1,500 gpm respectively, and a fire duration of four hours, fire storage calculates to an additional 600,000 gallons of storage. Required system storage would be 28.7 MG.

The table below shows the existing storage facilities in the City of Flint. The total storage available in the system is 57 MG located in three different areas of the city. The total system storage exceeds the required storage by just over 28 MG. While excess storage is sometimes advantageous from an operational stand point, the city currently has two times the required storage and is facing declining population, declining water use and declining revenues.

Table 11: City of Flint Storage Facilities

Location	Type	Capacity (gallons)	Overflow Elevation
Dort Reservoir	Ground	20,000,000	774.3
Cedar Street Reservoir	Ground	20,000,000	757
West Side Reservoir	Ground	12,000,000	779
Clear Well 3	Ground	3,000,000	724
Plant	Elevated	2,000,000	898

4.3 Water Pumping Facilities

The Ten State Standards requires that at least two pumping units be provided at each facility. With any pump out of service, the remaining pump or pumps shall be capable of meeting the maximum pumping demand of the system. Therefore we have used the following criteria in evaluating the system:

- The firm pumping capacity should provide projected Maximum Day Demand and fire flow of 2,500 gpm for four hours.

A. Pump Station 4

Pump Station 4 is located at the Dort Reservoir on the WTP grounds. The station currently has a total of five pumps, two of which are inoperable. The station's total capacity is 46 MGD with firm capacity of 26 MGD. Table 12 shows the pump characteristics for the operable pumps. The operable pumps were installed in 1994 and are now 19 years old.

Table 12: Pump Station 4 Facility

Pump No.	Design Capacity (MGD)	Type	Design Head (feet)
7	20	Turbine	185
8	20	Turbine	185
9	6	Turbine	185

B. Cedar Street Pumping Facility

Cedar Street Pumping Facility is located in the southern portion of the city on Cedar Street near Court Street. The station consists of three pumps, with a total capacity of 30 MGD and a firm capacity of 18 MGD. The station was constructed in 1948 and the existing equipment is all 1948 vintage. The station has exceeded its design life and has been scheduled for rehabilitation for several years. Table 13 shows the pump characteristics of the Cedar Street Pumping Station.

Table 13: Cedar Street Pump Facility

Pump No.	Capacity (MGD)	Pump Type	Motor Horsepower (HP)
1	12	Centrifugal	160
2	9	Centrifugal	160
3	9	Centrifugal	160

C. West Side Pump Station

West Side Pump Station is located on the west side of the city on Pershing Street. The station consists of four pumps, with a total capacity of 24 MGD and a firm capacity of 16 MGD. The pump station's four pumps were installed in 1970 and are now 40 years old. The pumps are approaching their design life of 50 years. The pump station has been scheduled for check valve upgrades for several years. Table 14 shows the pump characteristics of the West Side Pumping Station.

Table 14: West Side Pumping Station

Pump No.	Capacity (MGD)	Pump Type	Motor Horsepower (HP)
1	8	Turbine	142
2	8	Turbine	142
3	4	Turbine	142
4	4	Turbine	142

D. Torrey Road Booster Station

Torrey Road Booster Station is located on Hammerberg Road south of the Cedar Street Facility. The station consists of two pumps, with a total capacity of 6.8 MGD and a firm capacity of 2.8 MGD. The station is vintage 1954 and at 56 years of age, has exceeded its design life. The station has been scheduled for rehabilitation or replacement for several years. Table 15 shows the pump characteristics of the Torrey Road Pumping Station.

Table 15: Torrey Road Pump Facility

Pump No.	Capacity (MGD)	Pump Type	Motor Horsepower (HP)
1	4	Centrifugal	65
2	2.8	Centrifugal	100

Table 16: City of Flint Total Pumping Capacity Analysis

Pumping Station	Number of Pumps	Pumping Capacity (MGD)	Firm Capacity (MGD)
Dort (P.S. No. 4)	3	46	26
Cedar Street (P.S. No. 3)	3	30	18
West Side (P.S. No. 5)	4	24	16
Torrey Road	2	6.8	2.8
Total Pump Capacity		106.8	62.8

The City of Flint currently has a total pumping capacity of 106.8 MGD and a firm capacity of 62.8 MGD. Typically water systems have sufficient firm capacity to meet projected maximum day and the necessary storage to meet peak hour. The City of Flint currently has an observed maximum day of 26.38 MGD, which occurred in 2007. The observed maximum day for 2008 and 2009 were 18.66 MGD and 21.57 MGD respectively, and are significantly less than the 2007 figure. Based on projections shown in Table 17 below, the maximum day demand will continue to decline for the foreseeable future. The projected maximum day for 2010 is 26.2 MGD and based on that, the city has almost two and half times the firm capacity required to meet the needs of its customers.

Table 17: City of Flint Future Population and Water Usage Projections

2010	118,465	36,067	1,735	37,802	8,078		18,319		24,235	
2015	115,481	35,159	1,691	36,850	7,875	0.975	17,858	0.975	23,624	0.975
2020	112,234	34,170	1,644	35,814	7,653	0.972	17,356	0.972	22,960	0.972
2025	109,865	33,449	1,609	35,058	7,492	0.979	16,990	0.979	22,475	0.979
2030	107,663	32,778	1,577	34,355	7,342	0.980	16,649	0.980	22,025	0.980

Population projections from Genesee County Metropolitan Alliance
Information shown is for City of Flint only

4.4 Water Distribution System

As noted in Section 1.1 E, much of the City of Flint water distribution system is over 70 years old and is in need of rehabilitation or replacement. In addition, there is a significant amount of 4" watermain in the system that is over 70 years old, prone to watermain breaks, and unable to provide modern pressures and fire flows. The 20-year plan for the water distribution system is twofold: 1) rehabilitate or replace the primary transmission system that serves the city and 2) abandon 4" watermains where there is a suitable parallel main, or replace the 4" watermains with 8" in other cases.

4.5 System Pressures

The Ten States Standards recommends the following criteria for water systems:

- A minimum working pressure of 20 psi
- A normal working pressure of 60 to 80 psi
- Pressure reducing valves are to be provided when static pressures exceed 100 psi

In general, accepted minimum and maximum working pressures are 20 and 100 psi, respectively. Pressures below 20 psi do not provide adequate working pressure for firefighting needs and pressures in excess of 100 psi increase the risk of watermain breaks, and can cause issues in residential plumbing installations.

The city system generally operates between 40 and 75 psi and provides all customers with adequate flows and pressures to meet normal demands. Fire flow and pressure are substandard in some areas due to undersized mains and this has been addressed in the water distribution 20-Year Capital Improvement Program.

4.6 Emergency Back-up Water Supply

As discussed in Section 1.1 B, the City of Flint emergency backup water supply system is provided by the 36 MGD Water Treatment Facility located at Dort and Stewart. The facility has been recently rehabilitated and upgraded and can meet the city's current maximum day of 26.4 MGD and projected maximum day demands for the 2010 – 2020 study period. However, an estimated $25,000,000 of upgrades are planned to provide additional capacity and water softening.

In addition, Genesee County has requested 8 MGD in emergency backup water supply that would be delivered from Pump Station 4 to a point on the northern limits of the city, most likely in the Dort and Carpenter area. From that point the county would construct watermain and pressure boosting facilities to supply water to the GCDC-WWS system.

A. Standby Power Availability

The Flint Water System includes three pumping facilities that provide additional pumping to meet daily peak flow demands. These facilities are Cedar Street, West Side, and Torrey Road and the pumping capacities are listed in Tables 12, 13, and 14. The facilities currently do not have any standby power. The goal is to provide sufficient standby power to meet average day demands of the city in the most cost-effective manner.

West Side Station has a firm capacity of 26 MGD; Cedar Street Station has a firm capacity of 18 MGD; and Torrey Road has a firm capacity of 2.8 MGD. The current average day demand is 14.04 MGD and Cedar Street most closely matches firm capacity to average day demand. Therefore, it is

recommended that a standby generator be provided at the Cedar Street Facility in the event that the city remains on the DWSD system.

4.7 Distribution Model

The distribution model developed for this study was created from City of Flint GIS data using MWHSoft's InfoWater modeling software, an ESRI ArcView, GIS-based water modeling package. The model was updated to include water infrastructure improvements that have been completed since the previous model update in 1999-2000. The GIS-based model also provides the ability to include additional geographical information in the model such as valve locations, streets, parcel maps, contours, etc.

4.8 General

Water modeling is a computer simulation of water system infrastructure and demands. Water modeling can identify deficiencies in a system and evaluate the impact of alternatives for improvements. The parameters used for determining improvements include such items as providing adequate fire flows, increasing system reliability, serving future customers, maintaining a residual pressure of 40 psi or greater during PHD conditions, and evaluating system pumping and storage needs.

Water systems are analyzed, planned and designed through the application of basic hydraulic principles. Some important factors which must be considered when performing this analysis include:

- The location and size of supply facilities
- The location, size, and design of storage facilities
- The location, type, magnitude and variability of customer demands
- Water system geometry and geographic topography
- Minimum and maximum pressure requirements
- Anticipated fire flow requirements
- Land use

4.9 Hydraulic Water Model

The model is set up to simulate the existing City of Flint Water System as accurately as possible within the frame work of the software. Because the city operates the water system manually, the control schemes included in the model are limited and each run should be set to mimic specific boundary conditions including: pressure from Detroit; which pumps are on or off; GCDC demands; and appropriate tank and reservoir levels. The water model includes demand scenarios for the existing AAD, MDD, and PHD and projected demands for every five year increment from 2010 to 2030.

4.10 Physical Characteristics

The existing water distribution system facilities have been modeled using design information provided by the city. The model includes detailed information about the water system infrastructure including pipe

size, pipe length, c-factor, node elevations, pump curves, and tank and reservoir sizes. This information was collected from the city's GIS, City of Flint blue prints, and meetings with city staff.

4.11 Demand Allocation

The City of Flint demands were allocated in several ways depending on the information available and the level of potential impact on the accuracy of the model. Six sets of demands are included in the model:

1. Residential demands were developed from residential billing data and divided across the model;
2. Commercial/Industrial accounts with meters 2" and larger were analyzed for one year of data and the demand placed at the closest node to the account;
3. GCDC demands were developed using actual meter data from GCDC and City of Flint;
4. Small commercial demands were developed from billing data and spread across the system;
5. Unaccounted for water was analyzed in Table 6 and applied across the system.

4.12 Water Model Calibration

Model calibration is the process of evaluating the data incorporated into the model against real world flows and pressures in the water system. The accuracy of the process will vary depending on the accuracy of the information input to the model; the age and complexity of the water system; the accuracy of the boundary conditions; and the accuracy of the field data that is collected for calibration. The level of calibration accuracy that is required varies with the type of analysis being carried out. For the purposes of this study. values plus or minus 10 percent of field values were considered acceptable. The water model was calibrated using flow test information from the City of Flint conducted in the fall of 2009. The flow test sites were spread geographically across the system.

4.13 System Configuration Alternatives

A. Water Supply

Water supply and the water plant will be evaluated in a separate report.

B. Water Pumping and Storage Facilities

The existing City of Flint water system was designed to service a much larger population and significantly more industry than is currently being served. Steadily declining population, declining water demands, a much smaller General Motors presence, and GCDC-WWS's construction of out-county pumping and storage facilities have gradually reduced the demands on the city's water infrastructure. In addition, many of the city facilities are at or are reaching their design life and are poised to impact the water system budget and fund balance. There is significant excess pumping and storage in the system and some of this can be eliminated without impacting flows and pressures while lessening the burden on the budget and maintenance staff. The pump and fill ground storage system that the city operates is energy-intensive and additional elevated storage, that does not require additional pumping, is included in one of the scenarios. Based on these factors, three alternatives were

developed for the 20-Year Capital Improvement Program. The first alternative would keep the city water system as it is currently and provides a number of potential future configurations. The second alternative examines operating the system with the water plant as the source of water. The third alternative provides a preliminary view of the city and county combining the water systems and operating as one system.

1. Existing System Configurations

In the existing mode of operation, the city operates off DWSD line pressure to feed the round storage tanks in the system and then pumps from Cedar Street and West Side to meet peak demands. The City of Flint water system currently has excess pumping and storage capacity that is reaching its design life, costly to maintain, and not required in order to meet the design standards for the system. The following five tables show various configurations that would meet the system demands while reducing operating costs and facility upkeep costs.

2. Full-Time Water Plant Operation

This alternative examines the system configuration with the water plant operating as the main supply source for the city. The two alternatives for water supply are either from the Flint River or raw water from the Karegnondi Water Authority (KWA). In this alternative, the city would use the high service pumps at Pump Station 4 located on the water plant grounds to feed the system. Two of the existing pumps have been abandoned, and the remaining three are over 16 years old and are not sized to efficiently supply the system with water. The five pumps at Pump Station 4 should be replaced with appropriately sized pumps to meet current and future demands and the associated piping and electrical equipment upgraded as necessary.

As noted in Section 1 above, West Side Storage and Pumping Facility and Cedar Street are operated on alternative days to meet peak demands. This operating configuration is reasonable with the existing water supply system operating off DWSD pressure during nonpeak periods. However, with the water plant operating full-time re-pumping water from Cedar and West Side to meet peak demands this may not be the most efficient way to operate the system. Proposed elevated storage located on the south end of the city allows the water to be pumped from Pump Station 4 through the system, filling the tanks and the elevated storage tanks and providing peak hour supply and fire protection without additional pumping.

Table 23: West Side, Torrey, and Cedar out of Service - 2 New Elevated

System Demands			
Average Annual Day	14.04	MGD	
Max Day	26.38	MGD	
Peak Hour	42.12	MGD	
GCDC Backup			
Required Storage			
Fire Flow	0.60	MG	
System	28.08	MG	
Total	**28.68**	**MG**	
Water Stored

Clear Well 3	3	MG	
Elevated	2	MG	
Proposed Elevated	2	MG	
Proposed Elevated	2	MG	
Total Storage	**29**	**MG**	
Pumping Capacity	Total		Firm
Proposed Dort (P.S. No. 4)	64	MGD	48

3. Combine the city system with the GCDC-WWS system.

   Genesee County surrounds the City of Flint and has significant water infrastructure in place. There have been discussions between the parties regarding interconnects for the mutual aid of both water systems during emergencies. Interconnecting the systems for daily use could also have mutual benefit to both parties. The county has 3 MG of elevated storage with overflow elevations at 930 and 940, and a pumping facility in close proximity to the hospital district which could meet peak demands and aid in the elimination of the Torrey Booster. The city has the backup water plant that is capable of providing 36 MGD in the case of an extended shut down of the 72" transmission main from Port Huron. There are numerous configurations for combining the two systems, and an in-depth analysis of the two systems could result in capital and operating savings to both systems. The following table illustrates one possible configuration.

Table 24: West Side, Torrey, and Cedar out of Service - Use County Houran Facility

System Demands				
Average Annual Day	14.04	MGD		
Max Day	26.38	MGD		
Peak Hour	42.12	MGD		
Required Storage				
Fire Flow	0.60	MG		
System	28.08	MG		
Total	**28.68**	**MG**		
System Storage				
Dort Reservoir	20	MG		
Clear Well 3	3	MG		
Elevated	2	MG		
Houran	2			
Total Storage	**27**	**MG**

Dort (P.S. No. 4)	46	MGD	26	MGD
Houran	9	MGD	6	MGD
Total	**46**	MGD	**26**	MGD
Upgrade P.S. No. 4 for flexibility and reliability (2 - 8 mgd and 3 - 16 mgd)				
Use County Houran Storage Facility and Pumping				

C. Water Distribution System

There are a number of improvements identified in the 20-Year Capital Improvement Plan. Water modeling and discussions with the city resulted in the following 20-year CIP.

Project Number	Capital Improvement Projects	Design Schedule	Construction Schedule	Project Construction Cost	Project Contingency (35%)	Total Project Cost
	Major Booster Station Improvement Projects					
1	Torrey Road Booster Upgrades (In-house)	Design Complete	Construct 2010	$300,000	$141,000	$441,000
2	Water Pumping Station 3 Electrical and Controls Upgrade	Design in progress	Construct 2010	$900,000	$423,000	$1,323,000
3	Pump Station 4 Improvements	Design 2012	Construct 2013	800,000	$376,000	$1,760,000
	Sub Total			**$2,000,000**	**$940000**	**$2,940,000**
	Major Transmission System Improvement Projects					
4	28,000 LFT of 24" watermain, WTP to Dupont; South to University	Design Complete	Construct 2011	$10,000,000	$4,700,000	$4,410,000
5	15,500 LFT of 12" watermain; Saginaw Street, Flint River to Pierson Road	2010	2012	$3800,000	$1,786,000	$5,586,000
6	16,100 LFT of 12" watermain; Atherton Road, Van Slyke to Dort	2010	2013	$4,000,000	$1,880,000	$5,880,000
	Sub Total			**$18,800,000**	**$8,366,000**	**$31,166,000**
	Minor Transmission System Improvement Projects					
7	500 LFT of 6" watermain; Hamilton Ave, Mason St to MLK Blvd.	2010	2011	$50,000	$23,500	$73,500
8	1,650, LFT of 6" watermain; Sonny Ave, Dupont to Lawndale	2010	2011	$165,000	$77,550	$242,550
9	1500 LFt of 6" watermain; Walton St, Clairmont to Augusta	2010	2012	$150,000	$70,500	$220,500
10	1500 LFt of 6" watermain; East Blvd, Farmers Market to Park	2011	2013	$150,000	$70,500	$220,500
11	325 LFT of 6" watermain; Alexander Street, Taylor to Rankin	2011	2014	$32,500	$15,275	$47,775
12	1075 LFT of 6" watermain; Mack Street, Clio Road to Winona	2011	2015	$122,500	$57,575	$180,075
	Sub Total			**$670,000**	**$314,900**	**$984,900**
	System Maintenance Improvements					
13	Water Meter Replacement Program 3,000 meters/year		2010-2015	$3,000,000		$15,000,000
14	Hydrant Replacement Program 3,000 meters/year		2010-2030	$500,000		$10,000,000
15	Valve Replacement Program 3,000 meters/year		2010-2030	$250,000		$5,000,000
15	SCADA Improvements	2011	2012-2013	$250,000		$250,000
	Total CIP Costs			**$25,470,000**	**$9,620,000**	**$35,090,900**

4.14 Construction Costs

ROWE has compiled "Engineer's Opinion of Probable Construction Costs" for the water system improvements. The following considerations were made in compilation of the costs.

- ROWE assumed the cost estimates for all watermain also included the costs for installing:
  - Hydrants
  - Valves
  - Gate wells
  - Taps
  - Corporations, curb stop and boxes
  - All fittings (bends, tees etc.)
- ROWE assumed the water service leads were not included in the cost estimates. The cost for the service leads should be included in the proposed development construction costs.
- ROWE assumed pavement removal and replacement would occur for 60% of the watermain installed, while 40% would be installed in non-paved areas.
- ROWE assumed a 20% contingency of the total construction costs to account for any unforeseen construction costs including, but not limited to, bore and jack installations, de-watering, and poor soil conditions.
- ROWE assumed the surveying, engineering, legal and administration costs would be 20% of the total construction costs.
- ROWE completed cost estimates using 2004 dollars, and applied an inflation rate of 2% per year.
- ROWE did not include costs for obtaining easements, since there was no consideration of detailed watermain routing in this study. This should be performed during the design phase of the proposed improvements.
- ROWE did not include costs for time and effort by City of Flint personnel.
- ROWE assumed the DWSD could provide an adequate amount of water to meet all Flint water demands for all conditions.
- ROWE did not include costs for 3-phase electrical service

Section 5 - Recommendations

The City of Flint has indicated that its goal is to operate the system with the Flint Water Plant as the source of water and withdraw from the DWSD system. The water source for the treatment plant may be the Flint River or raw water from KWA. The following recommendations are based on this decision and are listed in order of importance.

5.0 Water Efficiency

The city's current water efficiency is 65%. Typically water utilities operate at 85-90% efficiency. An increase to 85% efficiency would result in increased revenues in the range of $1.5 million to $3.0 million annually.

Key tasks:

- Large meter testing program
- Meter replacement program
- Water billing system audit
- Watermain break and leak analysis study
- Repair, replacement, or reconditioning of those assets found to be in disrepair

5.1 Water System Storage and Pumping Capacity

The current water system has twice the storage and pumping capacity that is needed to operate the system. A number of options to reduce pumping and storage have been identified. Implementing these operational changes going forward will allow the city to operate more cost effectively and concentrate on upgrading and maintaining key infrastructure.

Key Tasks:

- Review scenarios and reduce pumping and storage
- Upgrade those facilities that are retained to operate more efficiently

5.2 Capital Improvement Programs

The Water Reliability Study outlines a number of potential capital improvements that may be constructed over the next 20 years. These capital improvements should be evaluated more closely as the city moves forward with changing water supplies. The priority of the capital improvements will change depending on the direction that the city chooses for water supply.

Key Tasks:

- Revise and reprioritize CIPs based on outcome of water supply decision

5.3 Valve Replacement Program

A $500,000 annual valve replacement program has been outlined in the Water Reliability Study. The replacement program concentrates on the most critical valves and putting in place a system to upgrade all valves over time.

Key Tasks:

- Implement Valve Replacement Program

5.4 Hydrant Replacement Program

A $250,000 annual Hydrant Replacement Program has been outlined in the Water Reliability Study. The program concentrates on the oldest hydrants first, and puts in place a long term program to upgrade all hydrants in the system over time.

Key Tasks:

- Implement Hydrant Replacement Program

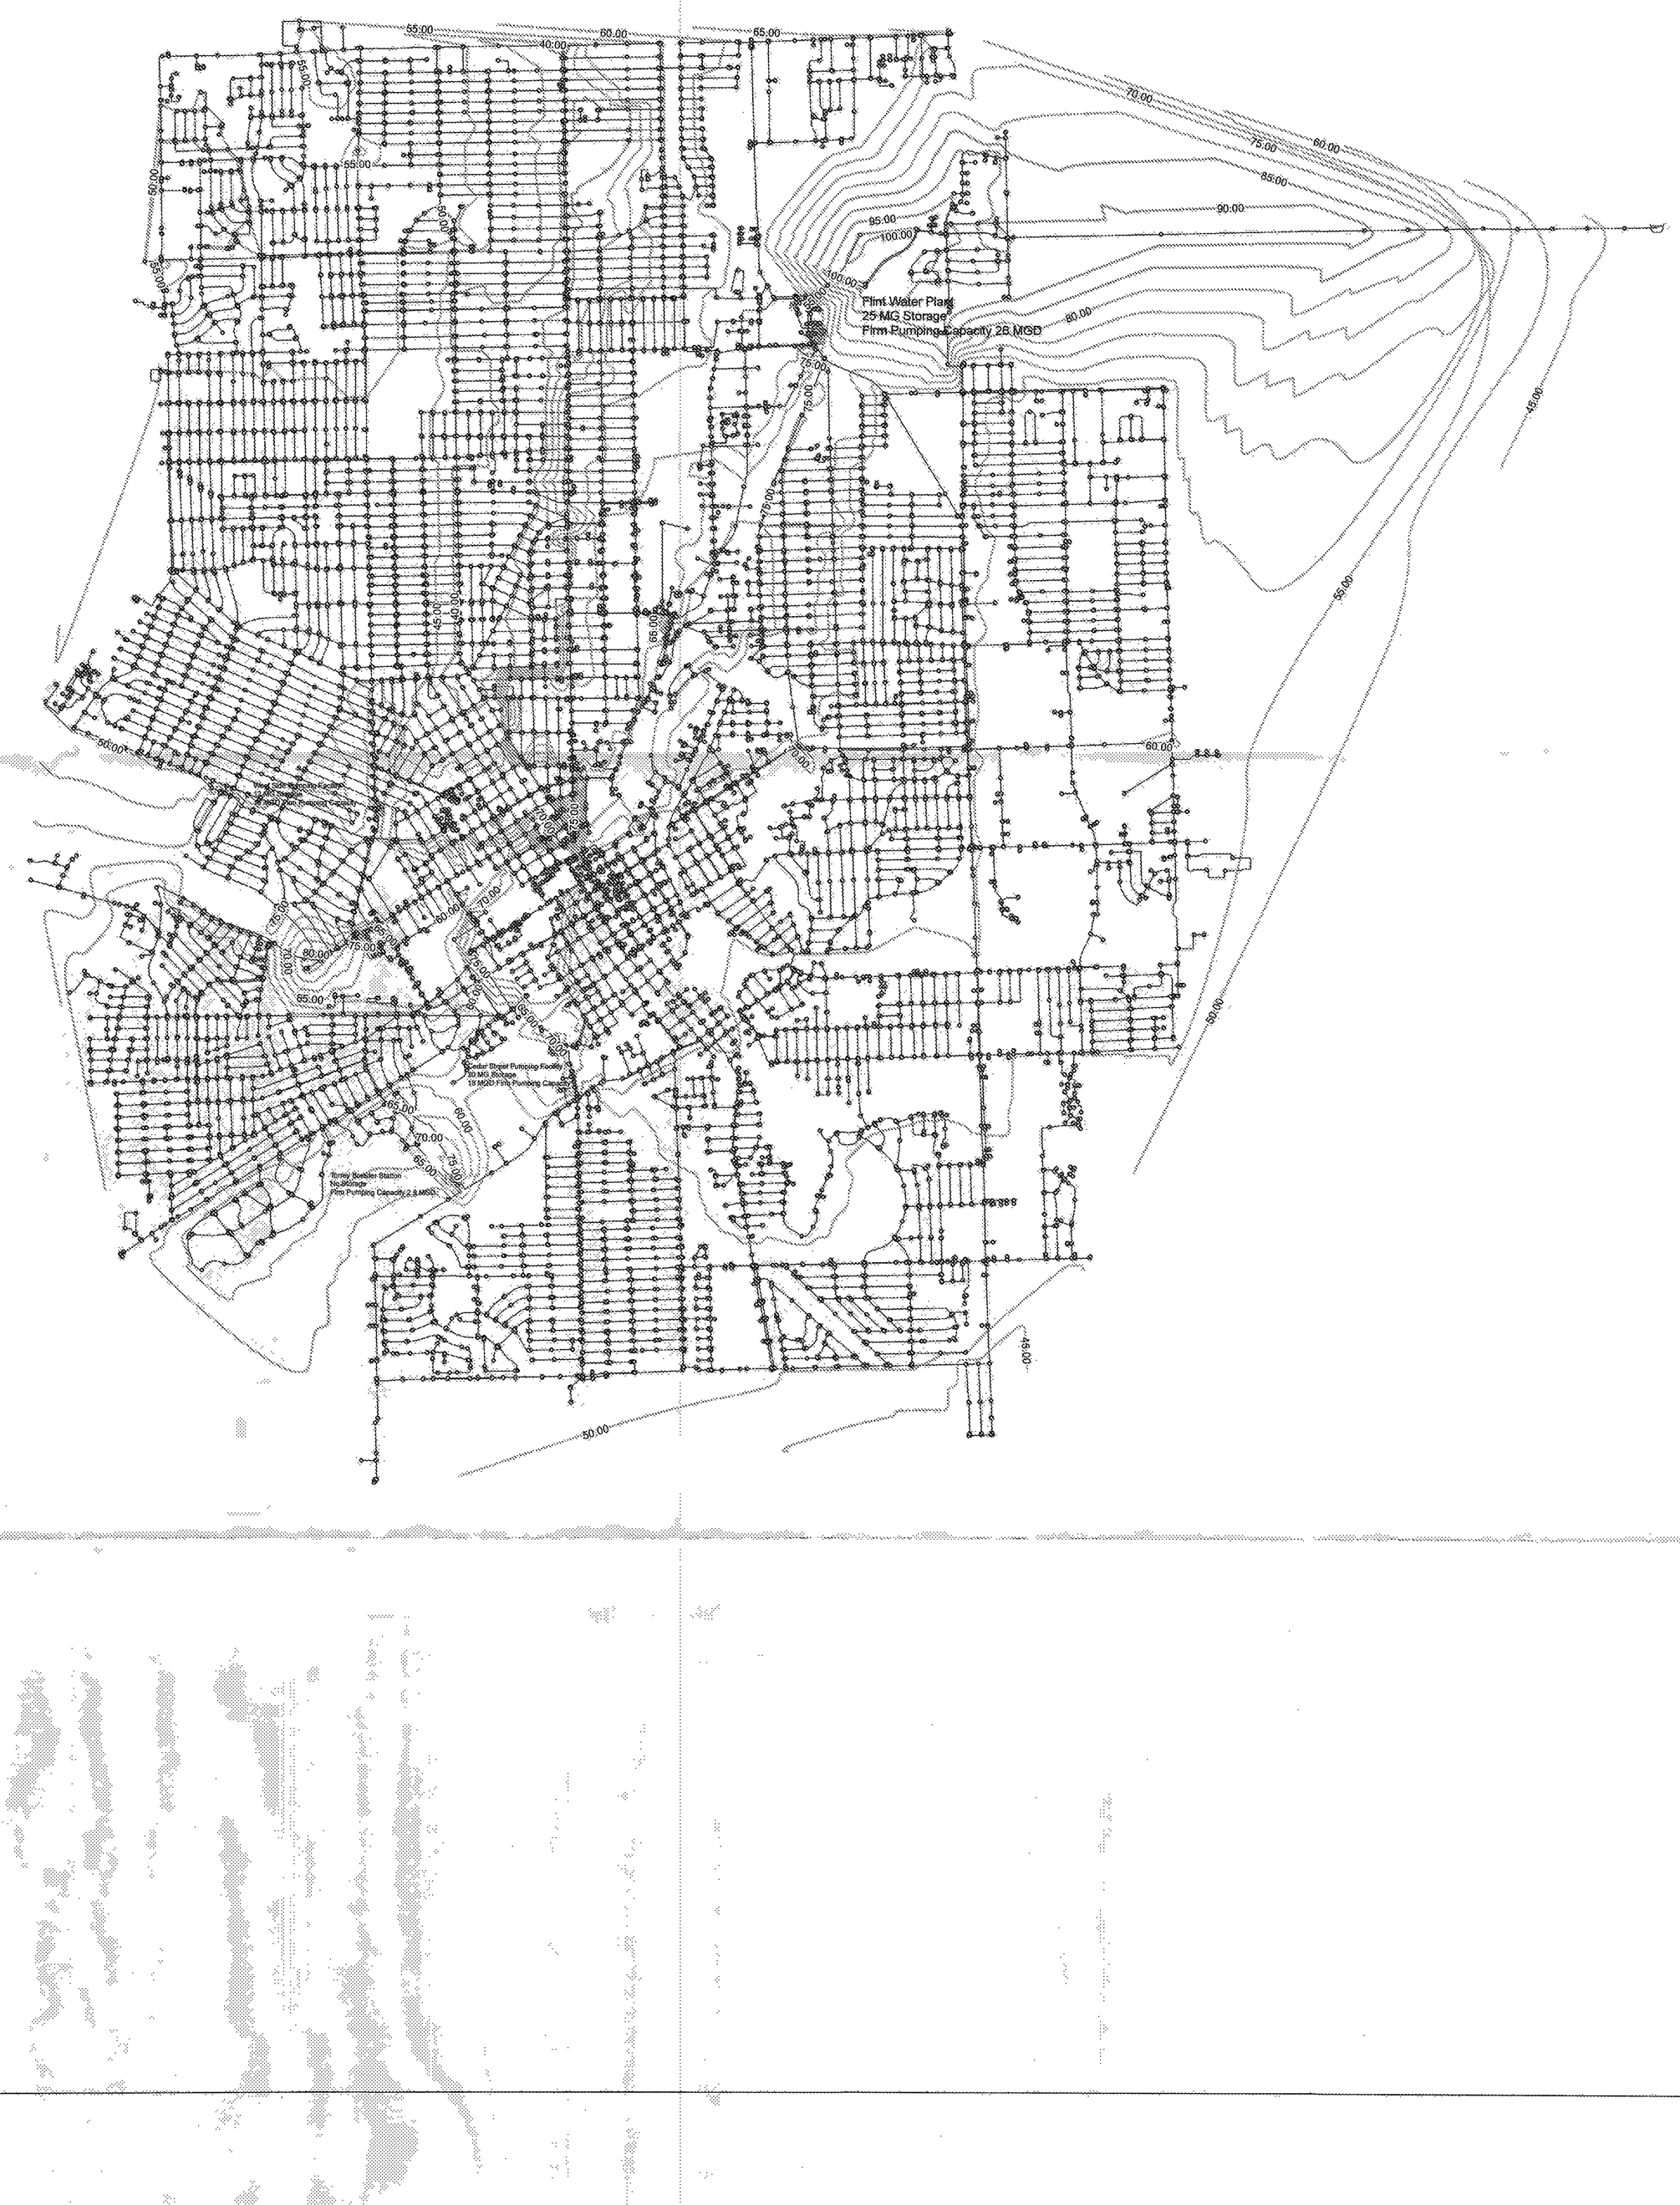
5.5 Water System Automation

Supervisory Control and Data Acquisition (SCADA) - Modern water utilities operate more efficiently and with lower labor costs by using SCADA to operate and analyze the water system and its operation.

Key Tasks:

- Evaluate and upgrade water system SCADA system
- Develop CIP costs to upgrade SCADA system
- Look at interoperability with GCDC-WWS SCADA system

5.6 GIS-Based Asset Management



One key to operating and maintaining a water system is identifying which assets are fundamental to operating the system, which require the most maintenance, and which are most likely to fail and what the effect of that failure will be. GIS-based work management and asset management systems provide the tools to easily perform these types of analyses and apply them to the system to make the most cost-effective capital improvements. The city has the basic GIS tools and water and sewer modeling software.

Key Tasks:

- Evaluate the various software packages
- Purchase software
- Implement software

City of Flint Water System
Average Day Pressure Contours
August 2011

June 7, 2012

I received a media inquiry from Mr. Ron Fonger from the Flint Journal concerning the city of Flint and the potential of blending treated water from the Flint River or Lake Huron with water purchased from Detroit. A summary of our discussion is provided below.

Q1. What permits or approvals are needed before Flint can make a large withdrawal (enough to be a source of drinking water) from a river?

A: The Karegnondi Water Authority (KWA) is required to obtain a Large Quantity Water Withdrawal Permit. This permit has already been obtained. The city of Flint; however, does not need to acquire a water withdrawal permit for use of the Flint River since the city already has an established baseline of 90 MGD. This was based upon fulltime operation of the Flint WTP and its pumping capacity prior to purchasing water from Detroit.

Q2: Will the DEQ allow Flint to blend water from the Flint River or from Lake Huron with water purchased from Detroit?

A: The city of Flint may elect to blend treated water from either source provided that the finished water quality distributed to the city Flint is comparable to the water currently purchased from Detroit. The finished water must meet all applicable drinking water standards.

Q3: What specific standards would need to be met?

A: The WTP must produce water that meets the turbidity standards and provides adequate disinfection contact time through the treatment process. I explained to Mr. Fonger the meaning of turbidity (the degree of clarity in the water) and that increased turbidity correlates to less effective treatment (removal of suspended particulates) which ~~will threaten~~ the bacteriological integrity of the treatment process and the ~~entire~~ water system. The WTP's finished water must also maintain a minimum chlorine residual as it enters Flint's distribution system.

Q4: As long as the drinking water standards are being met, does it matter whether Flint blends raw water from the Flint River or KWA with Detroit water first followed by subsequent treatment …or….treat the raw water first and blend it with Detroit water?

A: The most sensible sequence is to treat water from the Flint River and/or KWA followed by ~~subsequent~~ blending of water purchased from Detroit. This is the blending sequence that the city may consider.

Q5: Does the intake need to be permitted?

A: The Flint WTP has an existing intake in the Flint River; thus a new intake most likely does not need to be constructed. Other infrastructure improvements; however, will be needed ~~at and near the Flint WTP to accommodate blending Detroit water with treated water from the Flint River and/or KWA~~ and include;

new transmission piping, pumping stations, and treated storage. These and other improvements will require approval and issuance of a construction permit from our office.

Q6: Are there other communities in Michigan that blend water?

A: The city of Lansing and East Lansing (E. Lans-Meridian Water & Sewer Authority and Lansing Board of Water & Light) blend softened groundwater. Also, Ira Township and New Baltimore blend treated surface water. Each community; however, treats their own source of water prior to blending.

End of inquiry

Subject: questions regarding blending water

Mike:

What permits or approvals are needed before a community can make large withdrawls (enough to be a source of drinking water for a community) from a river?

Are there any permits or approvals required to blend water from a river with either treated or untreated water from Lake Huron?

Are any communities in the state currently blending water?

2011 Drinking Water Infrastructure Needs Survey and Assessment

User: brysbym@michigan.gov Role: State

System View

The System View shows detailed information on a specific water system. This page has four tab sections. The **Projects** tab shows all of the projects submitted by the water system. The **Details** tab shows water system specific information, including the water system's address, and water system contact information. The **Tracking** tab shows the history of the selected survey after the survey was returned. The tracking includes information such as where the survey has been located since it was returned, what phases of the upload process the survey has been through, and which analysts worked on each phase. The **Projects Table** tab shows all of the projects submitted by the water system in a view similar to the original paper survey pages.

Subject: RE: KWA Bin Classification

Mike,

We can't give them a conclusive answer, but we can provide them with some confidence that 73 of 75 subH treatment systems (including all Great Lakes sources) have been classified Bin 1 and allow them to move forward with their WTP design basis which is what they were asking for. As you said the official answer won't come until they do the actual monitoring.

Subject: RE: KWA Bin Classification

The only potential "fly in the ointment" could be the ground storage reservoir proposed to contain 7-10 days of storage. I would assume that crypto monitoring would be required at a location downstream of this impoundment prior to the WTP. The potential for problems at this location can be minimized depending on the nature of construction and how well it is managed. Also, samples for Crypto (representative of Lake Huron water) can't even be collected until the intake crib and low service station are constructed.

Subject: RE: KWA Bin Classification

All Subpart H plants that use the Great Lakes as a source of raw water were classified as Bin 1. The only plants in the entire state that were classified in a higher Bin were Deerfield and Blissfield, which use the River

Raisin as a source. Deerfield opted out of the monitoring and volunteered to go to Bin 4. Blissfield was place in Bin 2.

I would be shocked if KWA was placed in any other Bin than 1, but we will not know for sure until they participate in the 2nd round of Crypto monitoring which starts in a few years.

Subject: KWA Bin Classification

Pat,

We met with Genesee Co. today to go over the KWA project. One of the questions they had about the GCDC WTP was what bin classification they would fall into. We explained that no great lakes water intake has shown problems with crypto, but they would like some reassurance they won't be classified into something restrictive. Do you have a summary of the statewide LT2 data that we could forward to them?

Subject: RE: Flint Scenarios

Here are my comments on the attached documents:

- Currently Flint receives water from DWSD and uses their water treatment plant as a back-up. Flint is currently in compliance with the SDWA as they stand with regard to reliability/redundancy. There is no regulatory reason for leaving the DWSD system. The issue of KWA vs. DWSD is mainly a question of cost.

- The February 2013 TYJT report indicates that there are economically viable options that would allow Flint to continue to receive water from DWSD. There is conflicting information on costs depending on the source, and I really don't know which cost estimates are most correct. If there is a cost effective option for Flint to stay on the DWSD system, it should be pursued.

    - If Flint leaves the DWSD system, there will be ~30 miles of unused water infrastructure. The cost of maintaining excess water infrastructure and capacity in the DWSD system will be the burden of the customers that remain on the DWSD system.

    - The DWSD system has already undergone a significant reduction in water demand that continues to hurt their bottom line. The loss of an additional customer will only exacerbate the problem.

- Small water systems that receive water from the DWSD on the Imlay to Flint transmission line will likely be left to build their own water system (Imlay, Mayfield, Greater Lapeer Utilities Authority).

With regard to Flint's representation/decision making authority:

- For the last 10 years, DWSD has implemented a customer outreach program open to all customers known as the Technical Advisory Committee (TAC). TAC has developed Partnering agreements to work together on decisions regarding the DWSD system. The TAC has worked with DWSD to develop the latest rate structure, capital improvements program, etc. Historically, Flint has chosen not to participate on the TAC, but could do so going forward to make sure they have a say in the decisions relating to the DWSD system.

- DWSD is currently working on converting to a water authority. This new structure could allow for a seat on the Board of Water Commissioners.

Kris and Mike –

Note the assignment below, due next Wednesday morning at the latest.

City of Flint Water Supply Assessment
Tucker, Young, Jackson, Tull Inc.
February 2013

MDEQ – LDO Comments

1. DWSD's most cost-effective option of 8 MGD maximum day from either the Imlay Station or from FL-1 in Table 6-1 clearly causes the Flint WTP to exceed the 2:1 DWSD – Flint River blending ratio during maximum day demand and the high usage months in the summer. The need to soften during higher usage from the Flint River will increase capital improvement costs and on-going operation/maintenance costs at the Flint WTP.

   Additional capital improvement include:

   - Repairs to lime slakers and lime storage silos
   - Disposal of lime sludge residuals – on site de-watering/filter press system
   - Potential for higher Cryptosporidium Bin classification from the Flint River which will require more advanced treatment (UV disinfection, etc).
   - Flint WTP is rated at 36 MGD. Existing components (pumps, treatment basins, chemical feed systems) may not be suitable for treating at very low rates (8.0 MGD or less).

   Additional operational costs include:

   - Additional treatment chemical cost – lime-soda ash for softening
   - Additional electrical usage for increased ozone generation and softening
   - Additional system monitoring for increased levels of disinfection by-products

   The TYJT report does not address these additional costs.

2. The Average Unit Cost of purchased water from DWSD presented in Table 4-2 is misleading since the annual change was based on a hypothetical rate that Flint would be been offered had they signed a new purchase contract with DWSD. The actual annual change (average) of water purchased from DWSD by Flint is approximately 10.5% based on a rate analysis conducted by Flint and their consultant.

Hendrie P.S. 30 MGD
– 2 WWTP PS.

3. The TYJT report projects the cost of the pumping stations at $71 million and is approximately $40 million higher than KWA's cost estimate. KWA, Flint, and their consultant ~~provide accurate~~ construction costs ~~that would support their cost estimate~~. We would agree with TYJT's experience of higher construction costs in the immediate Detroit metropolitan area due to local construction costs and and requirements; however, these higher ~~are not always~~ applicable in out-state areas.

4. In Table 5-5 TYJT's estimate of $71 million and $218 million for the pumping stations and transmission main respectively includes their 30% ELAC estimate. TYJT; however, includes an additional $32.5 million for further ELAC costs and increases the total ELAC costs to approximately 43%. It appears that the ELAC is being double-counted and a 43% ELAC seems unwarranted for a project having a significant amount of preliminary design engineering completed.

5. Page 19 of the TYJT report states that under the KWA option, two separate treatment process streams would need to be maintained for the Flint River as a back-up supply. This is not true. The Flint WTP ~~could~~ use their existing KWA treatment train to treat Flint River water; however, some of treatment processes would need to be adjusted (increase coagulant and disinfectant dosages).

6. TYJT states on Page 15 that approximately $7.1 million in capital improvements will be needed at the Flint WTP for the KWA option based on the 2009 KWA preliminary engineering report. A decrease in these costs (KWA option) is likely as some of the capital improvements are not critical in the WTP's operation. However, additional capital improvements are needed if the WTP is utilized as part of DWSD's most cost effective blending option (see Item #1).

7. Page 18 of the TYJT report offers a second pipeline to Flint for redundancy along with sharing the capital cost of the new pipeline by all DWSD customers. How well will other DWSD customers accept this proposition?

8. The DWSD also offers to sell the existing transmission line to Flint for $4.7 million. What are the O&M costs of the transmission main? These costs do not appear to be included in the cost analysis. Will Flint be able to charge (sell) water to the Lapeer county customers that would then be purchasing water from Flint's pipeline? Finally, the pipeline is 50 year old, what is the remaining life expectancy of the pipeline and is this the best long-term investment for Flint? Why is the ~~Engr~~ Average cost of a pipeline repair on owner portion of the main?

9. Page 2 states that the 18 miles of pipeline from KWA to the Flint WTP is a 30-inch diameter main. The KWA Appendix 20 – October 2012 document states the pipeline is a 36-inch diameter main. The city of Flint is also investigating the proper size needed for this pipeline to meet their WTP's rated capacity and will be addressed in the final design.

10. Page 20 states that due to Flint's high water loss that the KWA pipeline will be oversized. KWA pipeline size is being based to meet an ca. 2030 projected water use & needs to be sized for same days of system expansion. MDEQ also doesn't take the position of downsizing sized capacity on the presumption that a utility will fix its internal infrastructure to reduce un-accounted water.

DEPARTMENT OF UTILITIES
Water Plant & Facilities

INTERNAL INSPECTION OF THE 72" TRANSMISSION MAIN MEETING

AGENDA

February 2, 2012
10:00 a.m. to 12:00 p.m.

1. Welcome / Introductions / Agenda Review

2. Monday February 6th

   - Start up of City of Flint's Water Treatment Plant
   - Closing of Genesee Rd. One or Two Lanes?
   - Locate and Saw Cut Road above Man-Way

   - Run all Next week
   - Map on exact location of each sect of pipeline

3. Tuesday February 7th

   - Excavation of Man-Way Completed by Evening
   - 11:00 p.m. Shut Down and Drain 72" Main

   6-8 hrs to drain
   1655 tons of Mud & blow-offs can be opened

4. Wednesday February 8th

   - Morning Pipe Line Drained and Removal of Man-Way Cover
   - 11:00 a.m. Jim Hegarty of Prein & Newhof Enter Pipe for Inspection
   - Afternoon Fill and Chlorinate Pipe Line between Bank and Valve on Meadowbrook
   - 11:00 p.m. put Line back in Service, Direct all Water to Dort Reservoir

5. Thursday February 9th

   - Work with Genesee Co. Road Commission on possible Vault and Manhole Cover for Man-Way and Repairs on Excavation

Develop Repair plan

Flint Water Plant & Facilities 4500 N. Dort Hwy. Flint, MI 48505 Phone: (810) 787-6537 Fax (810) 787-3710

- Enter pipe via mine excavation for cut & less disturbing of pipe.
- Then same when/location of leak & method of repair

other fix from inside or
clean everything up/ dig up & replace — city may not be able to expand

ECCS inputs

- may need to shut valve back to vassar
  then shuts down S. Gen P.T & S-Belsay P.T
- if Belsay rel valve operates — shut down only S. Gen PT

IE

- can enter manway & ~~Core~~ check & Hardwork
- then prepare to enter other manways as rel at Bank
- Possibility of road closures - cue. w. most Con. Trip

expect closure of Parking to be < 24 Hrs, but plan for 36 Hrs → Conc

Repair via "Slip line" — drive in cut off on ends of pipe line repair

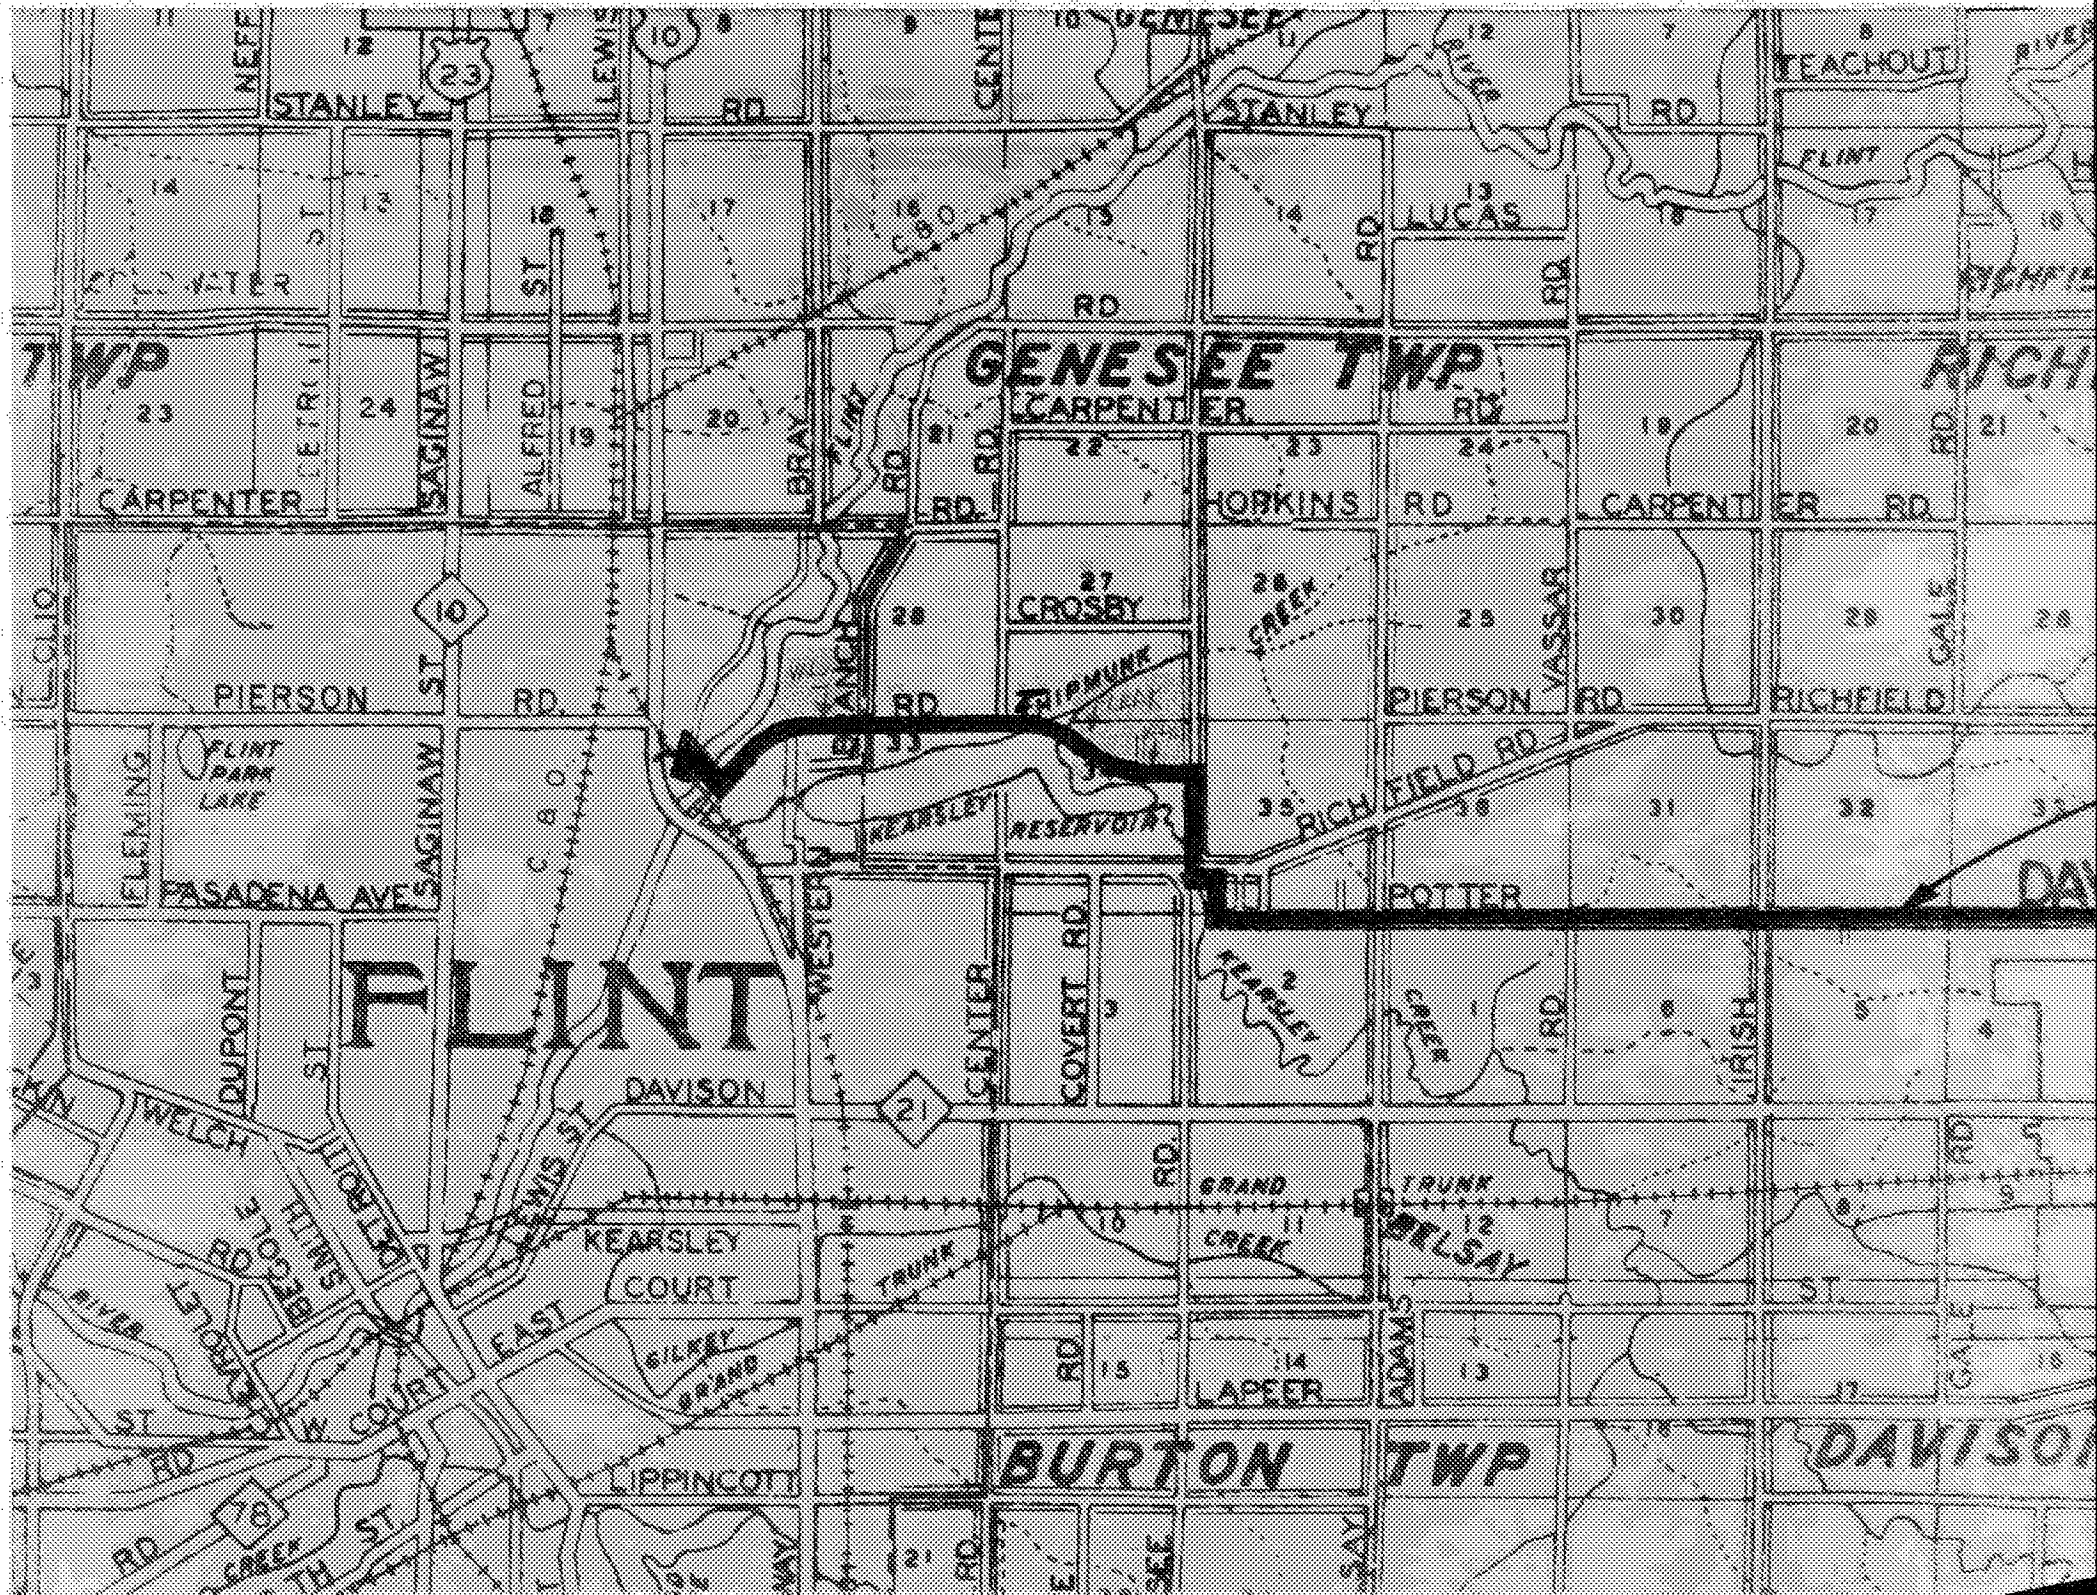
72-inch Transmission Main Repair
WTP Operation
City of Flint
2/2/12

1. Communication of events: Official(s) responsible for notification and subsequent updates.

   - MDEQ
   - GCDC & DWSD
   - Customer supplies
   - Media, LHD, Emergency operations
   - Water use reduction measures?
   - WTP operation (avoid BWA)

2. Inspection - Repair to 72-inch transmission main

   - Location, history
   - Contractor
   - Duration, extent, materials used (NSF approved?)
   - Oversight of repair



3. WTP Emergency Operation

   - Operational oversight
   - Operating status wrt to status of repair and distribution system status
   - Treatment rate
   - Ozone status
   - WTP turbidities
   - Post chlorination application/residual/demand
   - Intermediate chlorination
   - Bacteriological sampling; WTP plant tap, dist system
   - Distribution system chlorine residuals

4. Pipeline (Flint's portion) simplified schematic or diagram

   - Location of isolation valves, drain and blow-off structures.
   - Locations of previous leaks and completed repairs.
   - Location(s) of any additional leaks
   - Diagram to be updated as needed for use in future repairs

5. 90-day report - Outline of: discovery, cause, duration, correction action, areas affected, public notif, water reduction efforts, etc.

Subject: Follow-up regarding KWA proposal

John –

I had an opportunity recently to discuss with staff the proposed project to create an Authority to provide raw water to Genesee, Lapeer and Sanilac Counties. Staff indicated that it would be most helpful if you could provide an updated preliminary engineering report, as the document that they last received is dated September 2009. Once we have a chance to see the full scope of the proposed project, then staff will be in a better position to identify responsibilities.

At least initially, we do not envision having a single point of contact for permitting. We will, however, draw very clear lines of responsibility so that you will know who to work with on each portion of the project.

We look forward to working with you.

Liane J. Shekter Smith, P.E., Chief
Resource Management Division
Department of Environmental Quality

Subject: RE: Flint - Dept of Treasury

Great answers, Mike. The only comments/clarifications I have are in regards to the question on the use of the DWRF to operate the treatment plant full time. The DWRF may be used to construct facilities necessary to make full time operation feasible. However, it should be clear that "operating costs" are not eligible.

Also, any application to the DWRF requires a comprehensive, 20-year project plan, not a one-time, project specific request. The fact that the city of Flint recently turned down a DWRF loan even with a significant portion of it to be "forgiven" that was intended to address high priority distribution system needs cannot be overlooked. The city would have to include these needs in any revised/new project plan and satisfactorily explain any decision to not include these distribution improvements in this new loan application.

Subject: Flint - Dept of Treasury

I spoke with Mr. Randy Byrne from the Dept. Treasury – Office of Fiscal Resp. concerning the Flint WTP. Below is a brief summary of our discussion. I can fill you on more details this afternoon just prior or immediately after our KWA meeting.

Q1: The city of Flint has considered using the Flint River as a source of drinking water to be treated at their WTP; however,
The city may be somewhat reluctant to use the river as their source, what is your assessment of this issue?

A: The city could utilize the Flint River ranging from 100% utilization – to a certain percent blending (either Detroit or KWA) or
zero percent utilization of the river. I agree that the city should have concerns of fully utilizing the Flint River (100%) for the following; the need to soften, the potential for more advanced treatment after next round of crypto monitoring, available capacity in Flint River at 100-year low flow, residuals management (disposal of lime sludge). As the percent utilization of the river decreases (blending options), the need for softening, residuals disposal, capacity issues do not pose as much of a concern.

Q2: When comparing the treatment of Lake Huron water vs. Flint River water, are more treatment chemicals needed to effectively treat the water?

A2: Flint river water will require a larger amount of primary coagulant (Ferric) due to poorer raw water quality than Lake Huron water. Also, a different type of primary coagulant (Alum) may be more suitable for the treatment of Lake Huron water. I can confirm that based on what the Detroit Lake Huron WTP uses. Also, since softening would need to be employed, treatment compounds including lime, soda ash, and carbon dioxide would be necessary.

Q3: If the city needed to borrow money to be able to operate full time (KWA or blending), does the DEQ offer funding via the DWRF?

A3: The city could apply for DWRF funding and their eligibility would be based upon how well they score in the overall DWRF ranking process. Also, the total amount of the loan and their ability to repay the loan would be considered.

Q4: Flint has put forth a significant capital investment over the past 10 years to maintain their WTP, is the condition of the WTP sufficient for full time treatment of raw water from Lake Huron ? Are the operators qualified to operate the WTP?

A4: The Flint WTP has demonstrated its ability to treat raw water (Flint River) and meet the drinking water standards based on quarterly test runs since 2009 and two pipeline emergencies that occurred in 2009 where water from the WTP was distributed to the city. Successful operation of the WTP on an intermittent basis is difficult. WTP operators face the constant challenge of maintaining WTP components in good working order while the plant is normally out of service over 90% of the time. The reliability of WTP and its components are better maintained through continuous operation. The operating experience and knowledge of the operators is also better established with full-time operation. WTP operators have the required operator certification and are very familiar with the operation of the Flint WTP, meeting drinking water standards, and troubleshooting operational problems. The Flint WTP is capable of meeting the drinking water standard if the plant was utilized to treat raw water from Lake Huron.

Q5: Do you see any weak links in the WTP or significant improvements if the WTP were to be fully utilized?

A5: I would not see any major treatment changes or additions needed if Lake Huron water was utilized; however, in order for the city to fully utilize its storage capacity, a pumping station would need to be added immediately after the WTP such that treated water can be pumped into the city's 20-Mgal Dort reservoir. In the current configuration, water from Detroit flows by gravity through this reservoir and then into the WTP's 3 Mgal reservoir followed by pumping via Pump Station No. 4 into the city's distribution system. Improvement in stand-by power may also be necessary. Finally, if a component of Flint River water were to

be treated, then more advanced treatment based upon higher bin classification (UV disinfection, etc.) could be required based upon crypto. results.

Subject: Karegnodi Water Authority

On May 23rd, I met with representatives from Rowe Engineering and Lockwood regarding the proposed intake for the Karegnodi Water Authority. Initial plans for the intake line may be submitted to the SBD Office about July 1st. At a later date, plans may be submitted for the low lift pump station and raw water transmission line.

The consultants are proposing a ~85 MGD intake structure with a single 72-inch line going about a mile into Lake Huron. There will be two intakes and Douglas fir timber cribs. The internal velocity of the line and intakes will be less than 0.5 fps. About the only suggestions that I had for the firms was to ensure that any coatings used in the intake line meet ANSI/NSF Standard 60 and the line sending oxidants to the cribs be compatible for chlorine and sodium permanganate.

Following the meeting, I met with James P. Baker, the DNR Fisheries Division's Southern Lake Huron unit. Jim may be proposing some limitations on the work during the months of May (crappie) and November (lake trout).

RE: Analysis of Flint River as a Permanent Water Supply
Appendix 8: Cost of Service Study – Flint Water Treatment Plant

Dear Mr. Wright:

Attached please find a copy of Appendix 8 to the report referenced above. The appendix includes cost information for various WTP improvements related to operating the plant full time based on past reports and our discussions.

If you would like to discuss further, please contact me at 810-333-3201.

Best regards,
LOCKWOOD, ANDREWS AND NEWNAM, INC.

Jeffrey R. Hansen, PE
Project Manager

Enclosures: Appendix 8

Technical Memorandum
Cost of Service Study
Flint Water Treatment Plant

I. Introduction

This Technical Memorandum describes the proposed improvements needed at the Flint Water Plant to treat Flint River water on a continuous basis. The primary foundations for this evaluation were the "Water Treatment Plant Rehabilitation – Phase II" report dated December 2003 and the "Preliminary Engineering Report, Lake Huron Water Supply, Karegnondi Water Authority" dated September 2009. The findings, as presented in the following sections, address the improvements required for the water plant to produce finished water in conformance with the current federal and state drinking water regulations. In addition, operation and maintenance costs for continuous operation have been evaluated and included in order to determine the total cost associated with using the Flint River as a source of water.

Improvements, as proposed in this evaluation, along with those previously made during the Phase I improvements program, will produce a finished water quality equal to the current water quality as received from the DWSD. The design parameters are as follows:

1) Minimum Day Demand – 10-mgd
   Average Day Demand – 15-mgd (14-mgd in 2010 increasing to 15-mgd in 2050)
   Maximum Day Demand – 28-mgd

2) Turbidity – 0.20 NTU

3) Hardness – 80 to 100 mg/l as $CaCO_3$

4) Cryptosporidium – 3-Log Inactivation

5) Giardia – >3-Log Inactivation

6) Viruses – >4-Log Inactivation

7) Taste and Odor – Eliminated with pre-ozonation

8) Trihalomethanes – Less than 80 µg/l

9) HAA5 – Less than 60 µg/l

As part of this investigation, an inspection of the Flint Water Plant was performed on May 3, 2011. The purpose of this inspection was to determine if the recommendations in the Phase II report, as referenced above, needed to be revised due to changed conditions or water supply needs. Based on findings from this meeting, the major adjustment to be made is the reduction of average day demand from 20-mgd to 14-mgd and maximum day demand being reduced from 36-mgd to 28-mgd. Required improvements as recommended in this study have taken these new demands into account. The conceptual design of these new facilities would allow cost effective expansion to 36-mgd, as needed, to meet future demands.

II. Required Capital Improvements

The following describes the required improvements as required for the Flint Water Plant to operate on a continual basis using the Flint River as a water source. Most of these improvements are more fully described in the Phase II report and are not repeated to avoid duplicative effort.

A. Lime Sludge Disposal

Lime sludge is proposed to be pumped from the east and west softening basins to two new 42-ft diameter thickeners (25-ft SWD) located adjacent to the plate settling building. Decant from the thickener will flow by gravity to the primary clarifier influent channel. Thickened sludge (12% solids) will be pumped to a new plate-and-frame filter press located at the north end of the WTP 1 primary settling basin. A new two-story building would be constructed at that location to house the pumping facilities and presses. Each press, located on the second floor, will have a 225-cf per hour capacity and will drop the dewatered sludge into a first floor bunker area. The dewatered cake will be transferred to a lime storage concrete bunker located approximately 60 feet north of the sludge press building. The storage bunker (100-ft x 192-ft) will have the capacity to store three to four months of dewatered lime sludge cake. About every three months, contract haulers will remove the lime sludge and place on agricultural lands that are permitted for final disposal.

The capacities of these facilities are based on average day flow of 15-mgd, maximum day demand of 28-mgd and water quality softening requirements. Based on raw water quality data provided by the City of Flint, a lime dosage of 209 mg/l, soda ash dosage of 47 mg/l and carbon dioxide dosage of 37 mg/l were used to estimate lime sludge quantities and flows.

Opinion of Probable Cost:

Site and Access:			
Site Demolition	$	129,000	
Roadway Improvements	$	385,000	
Partial Settling Basin Demolition	$	129,000	
On-site Truck Scale	$	257,000	
Subtotal Construction:			$ 900,000
Construction Contingencies (15%):			$ 135,000
Design Contingencies (5%):			$ 45,000
Engineering, Legal, Bonds & Administration (17%):			$ 153,000
Opinion of Probable Cost:			**$ 1,233,000**

Thickener Basins - 42 ft Diameter:			
Two Thickener Mechanisms	$	310,000	
Two Concrete Basins (25 ft SWD)	$	513,000	
Two Geodesic Dome Covers	$	180,000	
Install Equipment	$	257,000	
Site Work	$	97,000	
Utilities, Piping and Process	$	193,000	
Subtotal Construction:			$ 1,550,000
Construction Contingencies (15%):			$ 232,500
Design Contingencies (5%):			$ 77,500
Engineering, Legal, Bonds & Administration (17%):			$ 263,500
Opinion of Probable Cost:			**$ 2,124,000**

Filter Presses and Building:

Two-225 cf Plate & Frame Press	$ 1,650,000		
Building (70 ft x 60 ft)	$ 3,331,000		
MEP	$ 1,089,000		
Site Utilities	$ 129,000		
	Subtotal Construction:	$	6,199,000
	Construction Contingencies (15%):	$	929,850
	Design Contingencies (5%):	$	309,950
	Engineering, Legal, Bonds & Administration (17%):	$	1,053,830
	Opinion of Probable Cost:	**$**	**8,493,000**

Lime Storage Bunker and Site Work:

12 ft Concrete Walls and Slab	$ 833,000		
Frame and Fabric Building Cover	$ 325,000		
Site Improvements	$ 385,000		
Front End Loader (5 cyd)	$ 308,000		
Site Utilities	$ 513,000		
	Subtotal Construction:	$	2,364,000
	Construction Contingencies (15%):	$	354,600
	Design Contingencies (5%):	$	118,200
	Engineering, Legal, Bonds & Administration (17%):	$	401,880
	Opinion of Probable Cost:	**$**	**3,239,000**
	Total for Lime Disposal :	**$**	**15,089,000**

B. Soda Ash Feed System

In order to remove the non-carbonate hardness, soda ash will be needed to meet the finished water hardness concentrations. Two new 800 #/hour feeders will be needed to meet the dosage requirements. Each of these feeders will be connected to the existing silos.

Opinion of Probable Cost:

Demolition of Existing Feeders	$ 20,000		
Two 800 #/hr Feeders	$ 112,000		
MEP	$ 109,000		
Chemical	$ 77,000		
New Pneumatic Fill System	$ 58,000		
	Subtotal Construction:	$	376,000
	Construction Contingencies (15%):	$	56,400
	Design Contingencies (5%):	$	18,800
	Engineering, Legal, Bonds & Administration (17%):	$	63,920
	Opinion of Probable Cost:	**$**	**516,000**

C. Additional Chemical Storage

During the Phase I improvements, the MDEQ did not mandate 30-day chemical bulk storage requirements since the plant was a redundant water supply to the DWSD. However, if the facility becomes a continuously operated treatment plant, then additional chemical storage must be added to meet the minimum storage volume requirements. To comply with the regulations, new oxygen, nitrogen and carbon dioxide storage facilities must be provided as follows.

Liquid Carbon Dioxide:
- Capacity – 34 tons
- Vaporizer – 750 #/hour @ 300 psig
- Piping – Schedule 80 Carbon Steel and Schedule 40 - 304L Stainless Steel

Liquid Oxygen

D. Electrical and SCADA Improvements

Section 9, relating to power and controls, of the Phase II study was prepared by Dmytryka Jacobs Engineers (DJE). The scope of the Phase II work did not include detailed investigations of the water plant site-wide power distribution nor the secondary power distribution within each of the facility structures. However, a number of observations and basic recommendations were presented in Section 9 by DJE.

The Flint Water Plant currently uses 2400V as primary power throughout the facility. All of the power feeders in the plant site are 5kV rated and it appears the existing switchgear is also rated at 5kV. Most of the major electrical improvements installed during Phase I were dual voltage (2400/4160) equipment in anticipation of the plant power being changed to 4160V in the near future. This change would allow the existing network of power feeders to handle approximately twice the power and would eliminate running new feeders to various portions of the plant.

The current sub-station has two 2.5MVA transformers running in parallel for a total capacity 5 MVA. These old transformers are not equipped with cooling fans. The full connected load to these transformers is estimated to be 6.97 MVA while the estimated power load at 36 MGD is 4.22MVA. Based on these estimates there is sufficient power for the plant with both sub-station transformers in service. Even though the transformers are owned by Consumers Energy, it could take weeks to replace one of these main transformers in the event of a unit failure, which will result in reduced treatment and pumping capacity. The sub-station switchgear was installed in 1960 and is antiquated and difficult to maintain.

The two existing Fairbanks Morse generators are currently inoperable and would cost approximately $1M to rehabilitate. The DJE team recommended installing two new emergency generators in lieu of re-building the existing units.

Section 9 of the Phase II report provides sufficient detail for the purposes of this report, but a detailed electric system evaluation of the entire plant should be performed prior to any major improvements to this facility.

While LAN did not perform a detailed review of the WTP electrical system during our site visit, it appears that all of the DJE findings are still pertinent. We, therefore, concur with the improvements as recommended by DJE in the Phase I report.

Opinion of Probable Cost:

Substation Upgrade	$ 961,000	
Standby Power Generation	$ 2,242,000	
Pump Station No. 4 Upgrade	$ 1,365,000	
Filter Press Building Feeder	$ 87,000	
WTP SCADA, Equipment & Programming	$ 720,000	
Telemetry System Equipment & Programming	$ 103,000	
Computers, Software & Training	$ 155,000	
Filter Transfer PS Power Feeders	$ 135,000	
Emergency PS Power Feeders	$ 145,000	
Subtotal Construction:	$	5,913,000
Construction Contingencies (15%):	$	886,950
Design Contingencies (5%):	$	295,650
Engineering, Legal, Bonds & Administration (17%):	$	1,005,210
Opinion of Probable Cost:	**$**	**8,101,000**

E. Post-Chlorination and Zebra Mussel Control

The previous report recommended changing the disinfection system from gaseous chlorine to sodium hypochlorite due to the potential for hazardous gas release and the requirements imposed by new federal regulations. Previous treatability studies have not addressed the potential impact of re-growth in the system due to ozonation by-products. These impacts should be addressed prior to proceeding with final plans for using river water.

The Flint River is known to be infested with Zebra mussels and mitigation measures will have to be implemented if the plant is placed into continuous operation. A sodium permanganate feed system is proposed to address these concerns.

Opinion of Probable Cost:

Demolition of Existing Equipment	$	39,000	
Storage Tanks	$	9,000	
Metering Pumps and Tables	$	11,000	
Piping, Valves & Tables	$	9,000	
Containment	$	59,000	
Installation	$	108,000	
	Subtotal Construction:	$	235,000
	Construction Contingencies (15%):	$	35,250
	Design Contingencies (5%):	$	11,750
	Engineering, Legal, Bonds & Administration (17%):	$	39,950
	Opinion of Probable Cost:	**$**	**322,000**

F. Security Issues

For water plant security issues, please refer to City of Flint Vulnerability Assessment. Details are omitted in this report due to confidentiality.

Not available at the time of the previous report, a source water monitoring system is included in the study due to recent advancements in technology. The proposed system design is based on Hach Model SC1000, equipped with UVAS, NH4D, pH, ORP, turbidity and DO probes.

Opinion of Probable Cost:

Security Improvements	$	145,000	
Source Water Monitoring System	$	95,000	
	Subtotal Construction:	$	240,000
	Construction Contingencies (15%):	$	36,000
	Design Contingencies (5%):	$	12,000
	Engineering, Legal, Bonds & Administration (17%):	$	40,800
	Opinion of Probable Cost:	**$**	**329,000**

G. PS No. 4 - Low and High Service Pumps

Section 7 of the Phase II report included recommendations to replace two of the low lift pumps and two of the high lift pumps along with various other improvements. During the site visit, it was apparent the condition of this facility has continued to deteriorate. Furthermore, with the reduction in water system demands, the various pump capacities are no longer properly sized to efficiently meet the new plant flow ranges. The pumps and motors are oversized and are operating outside their best efficiency ranges and should be replaced due to age, condition and cost to operate.

Additionally, some of these pumps cannot be operated due to excessive vibrations in the shaft and steady bearings. Existing vibration monitors are functioning as designed and are shutting the power off to the motors to avoid damage.

For low lift service, it is proposed to install two 10-mgd and two 15-mgd (nominal ratings) vertically mounted pumps equipped with low voltage inverter duty motors. The motors would be powered by low

voltage variable frequency drives. This will provide a firm rated capacity of approximately 35-mgd in low lift capacity.

For high lift service, it is proposed to install one 10-mgd, two 15-mgd and one 20-mgd (nominal ratings) pumps equipped with medium voltage inverter duty motors. These motors will be power by medium voltage variable frequency drives. This combination of pumps will provide a firm rated capacity of 40-mgd.

Opinion of Probable Cost:

Demolition of Existing Equipment	$	135,000	
Install Two (2) 10 MGD @ 40 ft of TDH Vertically Mounted Pumps with 125 HP, 480 V Inverter Duty Motor with 20 ft of Shaft & Steady Bearings	$	473,000	
Install Two (2) 15 MGD @ 40 ft of TDH Vertically Mounted Pumps with 150 HP, 480 V Inverter Duty Motor with 20 ft of Shaft & Steady Bearings	$	495,000	
Install One (1) 10 MGD @ 190 ft of TDH Vertically Mounted Pump with 450 HP, 4160 V Inverter Duty Motor with 20 ft of Shaft & Steady Bearings	$	245,000	
Install Two (2) 15 MGD @ 190 ft of TDH Vertically Mounted Pumps with 700 HP, 4160 V Inverter Duty Motor with 20 ft of Shaft & Steady Bearings	$	520,000	
Install One (1) 20 MGD @ 190 ft of TDH Vertically Mounted Pump with 800 HP, 4160 V Inverter Duty Motor with 20 ft of Shaft & Steady Bearings	$	285,000	
Piping, Valves, Supports & Bearings	$	480,000	
Intermediate Platforms, Ladders & Stairs	$	360,000	
Ventilation & Boiler Systems	$	340,000	
Install Three (3) Low Voltage VFD Units	$	85,000	
Install Four (4) Medium Voltage VFD Units	$	2,250,000	
Subtotal Construction:	$		5,668,000
Construction Contingencies (15%):	$		850,200
Design Contingencies (5%):	$		283,400
Engineering, Legal, Bonds & Administration (17%):	$		963,560
Opinion of Probable Cost:	**$**		**7,766,000**

H. Filter Transfer Station to Dort Reservoir and UV Inactivation

Under the requirements as outlined in the USEPA drinking water regulations addressing potential microbial contaminants, additional treatment technologies and enhancement of existing processes must be implemented to comply with these regulations.

As required under the enhanced surface water treatment rules, it is essential for water utilities to address giardia, cryptosporidium, viruses and bacteria in finished water. The level of treatment is dependent on

the source water classification. The City of Flint will need to perform a two-year source water study to determine the bin placement for the Flint River. For the purposes of this report, a Bin 4 placement was selected due to the nature of the watershed and, therefore, it is assumed enhanced Ct and UV inactivation will be required.

Reservoir No. 3 does not provide sufficient Ct to meet the current regulations, therefore, Dort Reservoir will need to be placed into the process train. Since Dort Reservoir does not match the hydraulic profile of the plant, an intermediate pump station will be required. This new facility will also include a UV inactivation system to comply with the enhanced water quality regulations.

This proposed facility, located west of the filters and south of Dort Reservoir, will house three 14-mgd (nominal rating) variable speed pumps with inverter duty, low voltage motors for a firm rated capacity of 28-mgd. Housed in a separate part of this same structure will be the UV system that will be equipped with three 12" medium pressure units with a rated capacity of 28-mgd.

Opinion of Probable Cost:

Site Work & Utilities	$ 77,000	
Building (80 ft x 60 ft)	$ 1,440,000	
Three (3) 14 MGD @ 40 ft of TDH, Vertically Mounted Pumps with 150 HP, 480 V Inverter Duty Motor	$ 535,000	
MEP	$ 940,000	
Valves and Controls	$ 205,000	
Install Three (3) 12" MP UV Units	$ 590,000	
UV Piping & Controls	$ 368,000	
Ventilation & Boiler Systems	$ 165,000	
Install Three (3) Low Voltage VFD Units	$ 85,000	
Piping Connections	$ 125,000	
200 ft of 30" Water Main	$ 200,000	
600 ft of 36" Water Main	$ 420,000	
Subtotal Construction:		$ 5,150,000
Construction Contingencies (15%):		$ 772,500
Design Contingencies (5%):		$ 257,500
Engineering, Legal, Bonds & Administration (17%):		$ 875,500
Opinion of Probable Cost:		**$ 7,056,000**

I. Emergency Interconnect Pumping Station

The City of Flint and Genesee County DWWS have entered into an agreement to provide 8-mgd of back-up service to each other under emergency conditions. There are several alternatives for pumping station locations and configurations to accomplish this interconnect. For the purposes of this report, a station located west of the filter building was selected as the most practical from and operational cost perspective. While the opinions of cost presented below indicate that these pumps will be housed in their own structure, it is feasible to house the pumps in the filter transfer station for potential savings.

Preliminary design for this pumping station include two constant speed 8-mgd pumps equipped with soft starts and medium voltage motors. A reverse flow control station will be included within the same structure to allow for flow from the DWWS to assist the City of Flint. Approximately three miles of 24-inch pipeline will be needed to connect the two systems.
Opinion of Probable Cost:

Site Work & Utilities	$ 90,000	
Building (32 ft x 24 ft)	$ 245,000	
Install Two (2) 8 MGD @ 290 ft of TDH, Vertically Mounted Pumps with 600 HP, 4160V Motor	$ 380,000	
MEP	$ 335,000	
Valves and Controls	$ 128,000	
Reverse Flow Control Station	$ 110,000	
Ventilation Systems	$ 35,000	
16000 ft of 24" Water Main	$ 4,992,000	
Subtotal Construction:		$ 6,315,000
Construction Contingencies (15%):		$ 947,250
Design Contingencies (5%):		$ 315,750
Engineering, Legal, Bonds & Administration (17%):		$ 1,073,550
Opinion of Probable Cost:		**$ 8,652,000**

The opinions of capital cost presented in the preceding sections are tied to an ENR Index of 8688 to match the September 2009 Lake Huron Water Supply Report. Furthermore, the contingency percentages included with each opinion of cost are the same as in the September 2009 report. The total opinion of probable project cost of these proposed improvements is as follows:

Lime Sludge Disposal		$ 15,089,000
Soda Ash Feed System		$ 516,000
Additional Chemical Storage		$ 2,057,000
Electrical and SCADA Improvements		$ ~~8,101,000~~
Post-Chlorination and Zebra Mussel Control		$ 322,000
Security Issues		$ 329,000
PS No. 4 - Low & High Service Pumps		$ 7,766,000
Filter Transfer Pumping Station & UV		$ 7,056,000
Emergency Interconnect Pumping Station		$ 8,652,000
Total Opinion of Probable Project Cost:		**$ 49,888,000**

III. Cost of Additional Operation

The City of Flint currently operates the water treatment plant periodically during the year to maintain the systems and to meet regulatory requirements. The water treatment plant is staffed with various classifications of employees to operate and maintain the facility for these minimal operations.

As part of this work, and to develop all costs of providing water service from the Flint River, it is necessary to determine the probable cost for operating and maintaining this facility for continuous operation. Water quality differences between the Flint River and Lake Huron are significant and require different treatment chemicals and dosages. Most noticeable is the fact that Lake Huron water does not require softening which negates the need for softening process and the associated lime sludge disposal.

The primary cost parameters that are included in this difference are labor, chemicals, residual disposal and electrical power. Each will be discussed in the following sections. These costs were projected through the year 2050.

A. Labor

Additional staffing was discussed and developed with representatives from the City of Flint to provide full time coverage on a 24/7/365 schedule, plus provide staff for residual management and operations of the various dams. Hourly rates and fringe benefits were based on current budget figures and inflated at a rate of 3% for future costs. The following table outlines the proposed staffing a cost for this operational element.

Classification	Number	Cost/Hr	Hrs/Year	Total	Fringe (%)	Total
Operators	12	$ 20.00	2080	$ 499,200	90.40%	$ 950,477
Maintenance	4	$ 25.00	2080	$ 208,000	90.40%	$ 396,032
Laboratory QA/QC	2	$ 24.00	2080	$ 99,840	90.40%	$ 190,095
Laboratory SDWA	2	$ 20.00	2080	$ 83,200	90.40%	$ 158,413
Planned Overtime	NA	MIXED	8320	$ 178,048	90.40%	$ 339,003

This estimate represents approximately $2,034,000 per year of additional labor.

B. Chemicals

Chemical costs are based on the projected average day water demand of 14-mgd and the average dose for each of the chemicals based on the raw water quality information and other operational records. Further, data from the previous treatability work performed during the Phase I improvements was also incorporated into these estimates. Chemical suppliers and other water utilities were contacted to obtain current chemical purchase costs which were adjusted by the ENR ratio back to an index of 8688. Where necessary, transportation costs to the Flint, MI area were included. The following summarizes the chemical costs associated with treating the Flint River water.

Chemical	Dose(mg/l)	Cost/#	Cost/ MGD
Ferric	44.50	$0.24	$89.07
Lime	209.00	$0.10	$174.31
Soda Ash	47.00	$0.29	$113.67
CO_2	37.00	$0.10	$30.86
Cl_2	3.00	$0.34	$8.51
Fluoride	1.00	$0.33	$2.75
Phosphate*	1.00	$0.51	$4.25
		Cost per MGD	$423.42

*Costs range from $0.51 to $0.96 per pound

In addition to the above, the cost of ozone will need to be added which is approximately $20.08 per million gallons per day per mg/l dose. This cost includes oxygen, nitrogen and power costs.

C. Residual Disposal

This category is divided into two groups: clarifier sludge collected in the plate settling basins and lime sludge from the softening process. The clarifier sludge is pumped from the clarifier basins by zone (six zones per train, three trains, total of 18 zones) to the plant main drain. As part of the Phase I work, the main drain was connected to a new wastewater pumping station located south of the filter gallery building. This pump station discharges the collected residuals to the city's sanitary sewer system. Nearly all of the filter wash water is recirculated back to the head of the ozone facility for re-use.

The cost to treat clarified sludge discharged into the sanitary sewer system is calculated as follows:

Plate Clarifier Sludge	
Flow (MGD)	14
SS (mg/l)	75
Primary Sludge (#/d	13,435
% Solids	2%
Sludge (gals/day)	80,500
Sludge (cf/day)	10,762

Based on the City of Flint's current wastewater charges of $1.00 per 100 cf, the annual cost would be $39,200 per year.

Lime/Soda Ash softening generates large quantities of residual wastes that have high disposal costs. The treatment proposed in this study involves pumping the sludge, at about 4% concentration, from the softening basins to two gravity thickeners, where it will concentrate to about 12% solids. After thickening, sludge will be pumped to the filter presses to be dewatered to approximately 55% solids. The filter presses will drop the cake into a lower bunker where it will be removed by an end loader to the main storage bunker. About every three months, the sludge will be loaded onto trucks and applied to agricultural land.

The volume of sludge is estimated as follows:

Sludge Production from Clarifier

Reaction	meq/l	meq/l as $CaCO_3$	meq/l as $Mg(OH)_2$
CO_2	0.25	0.25	0
$Ca(HCO_3)_2$	4.65	9.30	0
$Mg(HCO_3)_2$	0.30	0.60	0.30
$MgSO_4$	0.89	0.89	0.89
Excess Lime	1.25	1.25	0
Total meq/l		12.28	1.19
Less Practical Limits meq/l		0.60	0.20
Precipitate Produced meq/l		11.68	0.99
Precipitate Produced mg/l		584	49
Precipitate Produced #/MG		4872	412
Total #/MG		5284	

WTP Flow (MGD)	14	27		
Dry Sludge Production in #/day	73,983	142,681		
@ 4% Solids (gals/day)	221,771	427,701		
@ 12% Solids (gals/day)	73,924	142,567		
@ 12% Solids (gals/week)	517,466	997,970		
Dry Sludge Production (tons/week)	259		SG $CaCO_3$	2.71
Number of Hours per Week to Press	48		SG $Mg(OH)_2$	2.36
Dry Sludge Processed (#/hr)	10,789		SG solids	2.68
@ 55% Solids Sludge Processed (#/hr)	19,617			
55% Solids Sludge (#/cy)	2571		Sludge Solids =	55% as $CaCO_3$
@ 55% Solids Sludge Processed (cf/hr)	206		Sludge Unit Wt. =	95.22 pcf

Based on the preceding, 471 tons of softening sludge at 55% solids will be handled each week based on average flow and chemical dosage. Several Michigan water facilities were contacted to obtain lime sludge hauling and disposal costs. From this data a rate of $18.50 per wet ton was selected as a reasonable rate for disposal cost. This rate will result in an annual cost of $453,000.

D. Power

Practically all of the additional power costs are associated with low lift, intermediate transfer and high service pumping. Additional power costs will be used for process and handling of the softening sludge. The City of Flint is currently paying $0.07 per kwhr for service at the water plant. Power costs are calculated as follows:

TDH (ft) - High	190
TDH (ft) - Filter Transfer	40
TDH (ft) - Low	40
TDH Total (ft)	270
Pump Eff. (W to W)	80.00%
$/kwhr	$0.070
Pumping Cost Per MGD	$99.51
Solids Handling per MGD	$4.98
Total Power Cost per MGD	$104.49

Annual costs associated with the operation and maintenance of the Flint Water Plant are summarized in the attached tables following this section.

IV. Project Implementation Schedule

There are a number of issues that will impact the implementation schedule for this work. The source water studies to define bin number associated with cryptosporidium and giardia will take approximately two years. Part of these studies can be performed concurrently with design, but sufficient work will need to be performed to avoid impacting design schedule or work. A planning period of one year should be allowed for preliminary water quality and regulatory evaluations prior to initiating design work. Design of this project will require 10 to 12 months, with an additional three months required for permitting. After permits are received, allow three months for bidding and contract execution. Major equipment procurement and construction will take from 24 to 30 months. Plant commissioning will take about 2 months.

Total time required from notice to proceed to project completion 52 months to 60 months. This time frame does not include financing issues.

Public reporting burden for this collection of information is estimated to average 7.51 hours per response. This estimate includes time for reviewing the instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the information collected. Burden means the total time, effort, or financial resources expended by person(s) to generate, maintain, retain, or disclose or provide information to or for a Federal Agency. This includes the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information; adjust the existing ways to comply with any previously applicable instructions; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information. An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations are listed in 40 CFR Part 9 and 48 CFR Chapter 15.

Send comments on the Agency's need for this information, the accuracy of the provided burden estimates, and any suggested methods for minimizing respondent burden, including through the use of automated collection techniques to the Director, OPPI, Regulatory Information Division, U.S. Environmental Protection Agency (1804A), Ariel Rios Building, 1200 Pennsylvania Ave., NW, Washington, DC 20460; and Office of Information and Regulatory Affairs, Office of Management and Budget, 725 17th Street, N.W., Washington, DC 20503.

Source, Treatment, Storage, and Pumping Inventory

To ensure all potential source, treatment, and storage projects are considered, it may be helpful to complete some or all of this inventory table. However, completion of this table is not required.

- **Source Projects** are all projects related to collecting and pumping raw water. This includes wells, surface water intakes, springs, off-stream raw water storage, pumps, and well houses.
- **Treatment Projects** are all projects related to disinfection, filtration, or other treatment processes for ground or surface water sources, or for treatment applied in the distribution system.
- **Storage and Pumping Projects** are related to finished or treated water storage, and booster pump stations.

Inventory	Needing Replacement	Needing Rehabilitation	New Infrastructure Needs
Total Number and Capacity of Existing Wells or Springs:	Wells (pumps included) or Springs:	Wells (pumps included) or Springs:	Does your system have additional source water capacity needs to meet the needs of current users? ☐ Yes ☐ No If yes, how many additional sources are necessary?

Transmission and Distribution Inventory

Transmission and distribution projects are the piping needs of a water system. Projects for **valves, backflow prevention devices and assemblies, hydrants, and meters** that are not part of a transmission or distribution project listed in this table should be recorded in the table under the tab titled "Inventory Table 3".

On the table below, please provide an estimate of the total feet or miles of pipe in your system, if possible. Completion of this table is not required, but it may be helpful to ensure all potential transmission and distribution pipe projects are considered.

Note: The total feet or miles or pipe in your system is required information if any pipe projects are submitted based solely on survey-generated documentation (documentation codes 10 or 11).

☐ feet ☐ miles **Total Pipe in System** *(Check feet or miles)*

Total Pipe in System (Check feet or miles)		<=6 inch	8-12 inch	15-42 inch	>=48 inch

Meters, Service Lines, Backflow Prevention Devices/Assemblies, Hydrants, Valves, etc.

Projects for meters, service lines, backflow prevention devices and assemblies, valves, hydrants and other miscellaneous projects are recorded in this section to accommodate entries of multiple identical items on one line in the project table.

Record only projects that are not a part of another project (e.g., water main replacement projects will already include valves, hydrants and other appurtenances). EPA requires documentation of all projects provided. Applicable types of documentation are presented in List 4 of the Lists of Codes. Use only existing documentation of cost. We do not expect you to develop new cost estimates.

To ensure all potential projects are considered, it may be helpful to complete some or all of this inventory table. However, completion of this table is not required.

Inventory	Needing Replacement	New Infrastructure Needs

Total Number of Lead Service Lines:		

Climate Readiness
Supplemental Questions

If you used code 2G from List 3, in the "Regulation or Secondary Purpose" column of the survey, indicating that you have one or more projects that are related to climate readiness, please answer the following questions. Only one response is requested; do not provide a response for each project.

Projects that included a climate ready component [Project #(s)]: _____

Which of the following secondary consequences of climate change have contributed to your system's need for climate readiness projects? (check all that apply)

- ☐ Source water quality (e.g., water quality degradation affecting treatment processes, alternate sources)
- ☐ Source water quantity (e.g., availability affected by snowmelt or weather patterns, or hydraulic patterns)
- ☐ Infrastructure Vulnerability (e.g., facility locations affected by sea level rise, increased precipitation intensity)
- ☐ Other (please explain) _____

Please describe the data you are relying on to determine climate change consequences and implications.

- ☐ Model developed from state-specific data.
- ☐ Model developed from region-specific data.
- ☐ Other (please describe) _____

Respondent Information

Please provide the following information in case we need to contact you for clarification or additional explanation of any of your responses.

Contact Person (Person who completed this questionnaire):

Signature:		Telephone Number:	(810) 787-6537
Name (please print):	BRENT F. WRIGHT	Fax Number:	(810) 787-3710
Title:	WATER PLANT SUPERVISOR	E-mail Address:	bwright@cityofflint.com
Mailing Address:	CITY OF FLINT WATER PLANT	Best Time to Reach You:	M-F 7-4
(Street Address)	4500 N. DORT HWY		
	FLINT, MI 48505		

If you have any questions, contact your state coordinator or call the U.S. EPA toll-free Needs Survey Helpline at 1-877-367-9030.

CLOSING: Thank you for your help. Did you remember to?

- ☐ Attach all additional project tables to the questionnaire?
- ☐ Identify, by project number, available documentation for all needs and costs reported above?
- ☐ Put the questionnaire and the documentation in the pre-paid, pre-addressed Federal Express Pak provided and return this questionnaire and the documentation to the address below? (See the pink enclosure for further return instructions.)

Project Table

OMB No.: 2040-0274

Approval Expires: 02/28/2014

MI0002310

Using the completed inventory, capital improvement plans, or other existing planning documents and resources, please identify and document projects on the table below.

Source, Treatment, Storage, and Pumping Project numbers should start with Project #1000.

Transmission and Distribution Project numbers should start with Project #2000.

Backflow Prevention Devices/Assemblies, Hydrants, Service Lines, Valves, Water Meter, and Other Project numbers should start with Project #3000.

If a project is coded 2G for "climate readiness" from List 3, please refer to tab 6 of this workbook for supplemental questions.

Please do not include units. Refer to the header to determine the valid entry for the cell.

*If you have any problems, please call the DWINSA helpline at: **1-888-357-9030***

Prysby, Mike (DEQ)

From: Fisher, Brant (DEQ)

Sent: Thursday, March 15, 2012 2:38 PM

To: Shekter Smith, Liane (DEQ)

Cc: Lee, Lonnie (DEQ); Monosmith, Carrie (DEQ); Browne, Elizabeth (DEQ); Prysby, Mike (DEQ); Benzie, Richard (DEQ)

Subject: RE: Meeting with MDEQ March 20,21,22 or 26

Liane:

I don't see much need for my attendance. I have already addressed the water withdrawal issues with John O. The city of Flint has an established baseline capacity of 90 MGD (which they will never use) and the 85 MGD for the Karegnondi Water Authority (KWA) project was approved via application and issuance of a water withdrawal permit to Genesee County Drain Commission (GCDC) in 2009. The only thing to be aware of on the water withdrawal side of things is the some times talked about service to the village of Almont. They lie outside the Huron-Michigan basin and I don't believe water service to them would be covered by the existing water withdrawal permit issued to GCDC.

If you have any questions let me know - Brant

Subject: FW: Meeting with MDEQ March 20,21,22 or 26

Please see the note below.

Mike P., I'm assuming you'd be the lead on this project.

Who else needs to be included in this meeting? Looks like a significant change from our previous meeting. John O. is suggesting that Brock and Brant be included. Your thoughts?

Kelly – do you wish to participate at this time or wait until there's actually a proposal on the table?

Liane J. Shekter Smith, P.E., Chief

Subject: Meeting with MDEQ March 20,21,22 or 26

Liane-Flint wishes to meet with you etal on any day listed above. GCDC will also be in attendance. We wish to discuss the option for Flint City to Blend with DWSD water? Also, if they are allowed to blend what improvements, in the interim, until the KWA project is fully online [say 3 years]. Also, blending for 3 years and improving the Flint water plant, as a 365 day facility, using Flint River water, and they not join KWA? Other items for sure but in substance these are the main topics. We suggest at 1ish meeting. Mike Brown [EM] and his staff to present, GCDC in attendance and myself. Suggest Mike be in attendance, Brock, Benzie and maybe Brent as water quality and withdrawal maybe issues in play. If the Flint WTP is to be a 365 facility,using Flint river water, is there going to be a NPDES [withdrawal/dilution] issue at the downstream WWTP due to WTP withdrawal? Flint withdrawal rate to be 20MGD max. day.
Your thoughts. I called today and left a message with your assistant regarding this meeting.Also called Mike as it appeared your number had changed. Have not heard from Mike.
Let me know what is best for you and staff.
It appears, if Flint does not go with KWA, that GCDC and customers will go alone.
John O'

Preliminary Stats on Genesee County Legionellosis Investigation,

As of April 7, 2015

Number of lab-confirmed cases of Legionnaires' Disease: 45

Number of Pontiac fever cases: 1 possible

Total number of legionellosis cases: 46 - By June 2015

Geographic distribution:

45/46 Genesee Co (27 Flint, 6 Mt. Morris, 4 Burton, 2 Flint Twp, 1 Flushing, 1 Byron, 1 Davison, 1 Linden, 1 Otisville, 1 Vienna Twp)

1/46 Saginaw County (1 Chesaning)

Age range: 26-94 years

Average age (median): 62.2 years (63.5 years)

% Males: 50% (23/46)

Range of illness onset dates (n=45): 6/6/14-3/9/15

Number (%) of deaths: 15.2% (7/46); expect this number will increase as interviews are completed

Number (%) with other underlying comorbidities: TBD

Conference calls with Genesee County: Jan 27; Feb 10, Feb 19, Apr 7, 2015

Conference calls with hospitals: Jan 28, 2015

Date outbreak-specific survey completed and approved: 2/23/15

Number of cases interviewed: 21 completed (45.7%; 82.6% in total attempted/completed)

MDCH: 14 completed / 29 contacted (MDCH had 2 interviewers – now increased to 4)

Genesee: 7 completed / 10

Number (%) of cases hospitalized: 45/46 (97.8%). Number in ICU: 22/45 (48.8%)

Number (%) of cases hospitalized at McLaren: 18/45 (40%)

Number (%) of cases hospitalized at Hurley: 14/45 (31%)

Number (%) of cases hospitalized at Genesys: 6/45 (13.3%)

Number (%) of cases hospitalized at other hospitals outside Flint: 7/45 (15.6%)

Number (%) of cases who had been hospitalized in 2-weeks prior to onset: 20/45 (44.4%)

Number (%) of cases who had been hospitalized in 2-weeks prior to onset at McLaren: 16/45 (35.6%)

Number (%) of cases who had been hospitalized in 2-weeks prior to onset at Hurley: 2/45 (4%)

Number (%) of cases who had been hospitalized in 2-weeks prior to onset at Genesys: 0

Number (%) of cases who had been hospitalized in 2-weeks prior to onset at other hospitals: unknown

Number (%) of cases who had a short-term visit to a hospital in 2-weeks prior to onset:

Number (%) of cases who had a short-term visit to McLaren facility in 2-weeks prior to onset: 5/45 (11.1%)

Number (%) of cases who had a short-term visit to Hurley facility in 2-weeks prior to onset: 1/45 (2%)

Number (%) of cases who had a short-term visit to Genesys facility in 2-weeks prior to onset: 0

Number (%) of cases who had been hospitalized or who had a short-term visit to a hospital facility in 2-weeks prior to onset:

Number (%) of cases who had been hospitalized or who had a short-term visit to a McLaren facility in 2-weeks prior to onset: 21/45 (46.7%)

Number (%) of cases who had been hospitalized or who had a short-term visit to a Hurley facility in 2-weeks prior to onset: 3/45 (6.7%)

Number (%) of cases who had been hospitalized or who had a short-term visit to a Genesys facility in 2-weeks prior to onset: 0

Number (%) of cases who work outside the home: 8/46 (17.4%) [min of 72% at home]

Number (%) of cases who are retired: 20 (43.5%)

Number (%) of cases who are unemployed: 7/46 (15.2%)

Number (%) of cases who are disabled: 6/46 (13%)

Number (%) of cases whose occupation status is unknown: 5/46 (10%)

Jeff Wright

GENESEE COUNTY, MI -- L. D'Agostini & Sons Inc., a Macomb-area contractor, says it can build a **massive intake into Lake Huron (http://www.mlive.com/news/flint/index.ssf/2012/10/beneath_the_surface_her** for $24.6 million, the first step toward construction of a new water pipeline.

County Drain Commissioner Jeff Wright said he was "very, very pleased" with the results of the five bids opened Tuesday, Feb. 27.

Three of the bids to do the job for the Karegnondi Water Authority were for less than county engineers had estimated -- $27 million.

Wright stopped short of announcing L. D'Agostini & Sons as the low bidder, saying his office was examining bids and supporting documents in conjunction with a county water and waste advisory board.

The drain commissioner's office would recommend the low bidder be awarded the contract, provided the company's bid and paperwork are in order.

MLive-Flint Journal could not reach a representative of L. D'Agostini & Sons of Macomb Township for comment Wednesday, Feb. 27.

"We hope to make a decision shortly," Wright said in a news release. "I believe the bids were competitive, and within the projected range of what we expected, if not lower."

Karegnondi is the regional water authority that includes Genesee, Lapeer and Sanilac counties and the cities of Flint and Lapeer.

The authority was formed to build a new water pipeline to Lake Huron, putting those communities in position to supply their own fresh water rather continuing to purchase treated water from the city of Detroit.

County officials have said they intend to build the pipeline regardless of whether the state of Michigan allows the city of Flint to join the authority.

Wright said construction of the intake could begin in spring.

The first phase of building the pipeline is a massive undertaking in itself, requiring divers who will connect sections of a 72-inch-diameter intake pipe underwater and the use of power augers to open tunnels under the beach and lake floor.

The entire pipeline project's estimated cost is $274 million.

Here are the bidders for the intake work, according to the drain commissioner:

- L. D'Agostini & Sons, Macomb Township: $24.6 million
- Schoolcraft Constructors, Inc., Livonia: $25.8 million
- Southland Mole JV, Fort Worth, Texas: $26.8 million
- Ric-Man/Super Joint Venture, LLC, Sterling Heights: $27.9 million

Proposed Agenda
KWA and Flint Water Plant Issues
March 20, 2012 – 1:00 p.m.
MDEQ – Constitution Hall

- Attendees
  - Introductions and sign-in

- Updates and current status of KWA – Lake Huron raw water initiative

- Discussion on blending treated water from Detroit with Flint water plant effluent
  - Flint River Study – capacity and dilution factors for waste water treatment plants (If Flint represented at meeting)
  - Interim operation during KWA construction

- MDEQ concerns over redundant water supply to Genesee County

- MDEQ guidelines for intake permitting process:
  - Permit requirements to allow construction of intake to begin in August or September 2012
  - Likely MDEQ staff assigned to review and permitting

2 Actions to take to DWSD

1. — Buy 72" line & run as Lake Source
— & use River as redundant source

2. — Acquire for Full time use

Talk us your reliability reqts —
Redundancy to meet Avg day

3. No sell 72" line — Buy
Run Full KWA line

4. Verify HAM DAM Level
Confirm they HAM DAM does not need to be expanded

Water and Sewer Cash Flow with DWSD

	Year 1 FY13	Year 2 FY14	Year 3 FY15	Year 4 FY16	Year 5 FY17	Year 6 FY18	Year 7 FY19	Year 8 FY20
Current DWSD & FWTP Costs	$ 14,413,858	$ 15,355,135	$ 16,365,534	$ 17,450,717	$ 18,616,651	$ 19,870,650	$ 21,219,435	$ 22,671,185

Cash Flow Difference: KWA and DWSD

	Year 1 FY13	Year 2 FY14	Year 3 FY15	Year 4 FY16	Year 5 FY17	Year 6 FY18	Year 7 FY19	Year 8 FY20
Annual Cost: DWSD - KWA	$ (581,400)	$ (581,400)	$ (581,400)	$ 2,651,305	$ 3,431,128	$ 4,279,711	$ 5,202,809	$ 6,207,488
Cumulative Gain with KWA	$ (581,400)	$ (1,162,800)	$ (1,744,200)	$ 907,105	$ 4,338,433	$ 8,618,144	$ 13,820,953	$ 20,028,541

(1) This projection assumes that KWA begins delivery of water to Flint starting in July, 2016. Any interest on the bonds will be capitalized until that period. The City will be obligated to begin paying its entry fee of $581,400 in FY13.

(2) Cost of KWA option is projected to be $907,105 or 15% LESS than DWSD in the first year of operation (Year 4)

(3) Cost of KWA option is projected to be $6.2 million or 27% LESS than DWSD in the 5th year of operation (Year 8)

(4) Cumulative savings by the 8th year from the beginning of the project are projected to be $24 million

Detail of Original Cost Projections

Cost Comparisons: Water Supply to City of Flint from DWSD and proposed KWA project

Cost of Water to City of Flint (excluding Genesee) using continued service from DWSD

	FY13	FY14	FY15	FY16	FY17	FY18	FY19	FY20
Fixed Cost (1)	$ 4,411,680	$ 4,852,848	$ 5,338,133	$ 5,871,946	$ 6,459,141	$ 7,105,055	$ 7,815,560	$ 8,597,116
Escalator	1.1	1.10	1.10	1.10	1.10	1.10	1.10	
Commodity Cost (2)	$ 7,276,640	$ 7,640,472	$ 8,022,496	$ 8,423,620	$ 8,844,801	$ 9,287,041	$ 9,751,394	$ 10,238,963

Escalator				1.00	1.00	1.00	1.00	
Flint WTP Operating Cost (4)	$ 5,911,538	$ 6,207,115	$ 6,517,471	$ 6,843,344	$ 7,185,511	$ 7,544,787	$ 7,922,026	$ 8,318,128
Escalator	1.05	1.05	1.05	1.05	1.05	1.05	1.05	
KWA Commodity Charge (5)	$ 759,200	$ 797,160	$ 837,018	$ 878,869	$ 922,812	$ 968,953	$ 1,017,401	$ 1,068,271
Escalator	1.05	1.05	1.05	1.05	1.05	1.05	1.05	
TOTAL	KWA NOT AVAILABLE			**$ 14,799,412**	**$ 15,185,523**	**$ 15,590,939**	**$ 16,016,626**	**$ 16,463,597**

(1) The City will, upon joining, be required to pay a fee of $32,300 per MGD for each year until bonding for the project is obtained. At 18MGD, the City's cost is $581,000 annually. It is projected that fee will be assessed for 3 years.

(2) Per KWA proposal, project cost is $272 million. City's fixed cost would be 30% of debt service, based on capacity design of 60mgd, of which 18MGD is for Flint. Debt service is based on 5% interest rate @ 25 years; 5% added to principal for capitalized interest for FY13, FY14, and FY15. ($272,421,588 plus $13,621,078 for 3 years = $313,284,792)

(3) Per KWA proposal, the cost of upgrading the Flint is $6 million. City's fixed cost would be100% of debt service based on 5% interest rate @ 25 years), with 5% added to cover capitalized interest for FY13, FY14, and FY15. (total principal = $6.9 million)

(4) Per FY13 Budget annual cost of WTP is $4,111,538. $1.6 million for electricity and chemicals & 2 FTE's are added. 100% City cost. 100% of

(5) Per KWA proposal, initial commodity charge would be based on $1.30/unit or 7,500 gallons. Charge is based on 12MGD.

Flint, Michigan

517 843-2314

Gentlemen:

Over the last several months, governed by a process laid out by the State of Michigan, the Detroit Water and Sewerage Department (DWSD) has proposed a number of alternatives for long term water supply to the City of Flint. Each alternative was offered in the spirit of working in earnest to address the needs, priorities and concerns of the City of Flint and each provided an immediate cost reduction when compared to the current costs of water purchased from DWSD. In the final analysis conducted by Flint, these proposals did not overcome the desire for the Flint/Genesee region to be served by the same system and to have a voice in the future decisions governing the provision of water to this region.

Many of the proposals DWSD has made to Flint during this period are applicable to Flint/Genesee County or KWA with adjustments to demand and use requirements and would provide similar overall benefit. These options remain available for further discussion should the parties' desire. These prior proposals are included in summary form in Attachment 1 as an expanded table 6-1 from the February 2013 State of Michigan Contract No. 271N3200089, City of Flint Water Supply Assessment, submitted by Tucker, Young, Jackson, Tull, Inc. For comparison purposes only, DWSD's new proposal (Flint's 30% allocated share) is inserted.

The proposal scenarios outlined today offer a public/public partnership with options tailored to Flint/Genesee County or KWAs interests. For ease of writing, the remainder of this memo will present this proposal to KWA. Two basic scenarios are presented for consideration, both of which contemplate that KWA would enter a multi-year contract. Service commitments and usage definitions would be negotiated in the same manner as employed that have resulted in new contracts for other customers.

In brief, the proposal provides a unique opportunity to reserve capacity at DWSD's Lake Huron Water Treatment Plant and to participate in decision making for facility operation and capital investment through a joint operating committee. The proposal envisions that KWA would enter into a 30-year contract to purchase treated water directly onsite at DWSD's Lake Huron Water Treatment Plant.

In Scenario 1 the purchased water can either be pressurized or unpressurized. This first scenario results in a "supply only" rate schedule, with a "standby delivery" component to provide for emergency service at the existing Baxter / Potter connection. This scenario provides KWA the ability to construct new transmission owned and operated by KWA.

Scenario 2 maintains the public/public partnership concept and extends it to transmission facilities through which the Lake Huron Water Treatment Plant provides water. This scenario results in a "full service" rate schedule. The standby delivery component is eliminated, since the rate structure to KWA includes costs associated with the transmission system between the Lake Huron Water Plant and the Baxter / Potter connection.

DWSD proposes a modified rate schedule for the customers currently served through the contract with the City of Flint, which includes Flint and Genesee County. This modified schedule is intended to facilitate negotiations for a new water service agreement with the Karegnondi Water Authority (KWA). The scenarios presented herein represent the innovative thinking that DWSD and its new leadership are bringing to the table. Our goal is to provide the lowest cost water solution for the KWA service area.

The potential rate structures are introduced in summary form herein, with preliminary calculations using the proposed rate structures with FY 2013-14 as a baseline. These calculations and the accompanying discussion are based on the assumptions regarding contract terms that approximate recent discussions amongst the parties.

The proposal introduces the concepts, but does not definitively present all of the specifics, appreciating that such specifics are best addressed through negotiations designed to produce a new contractual agreement satisfactory to all parties.

[Remainder of page intentionally left blank]

Scenario 1 – Lake Huron Direct Supply Purchase:

- KWA enters into a long term partnering arrangement with DWSD to purchase all of its primary water supply directly at the DWSD Lake Huron water treatment plant.
- Supply rate schedule is designed to recover only water treatment revenue requirements. This rate schedule does not contain any delivery costs (pumping, transmission, storage, etc.).
- Supply rate schedule is computed based on specific costs associated with the Lake Huron Plant. No other DWSD revenue requirements, including those associated with other DWSD water plants, are included in the rate to KWA.
- Revenue requirements are separated into capital recovery and operation and maintenance expense elements. Baseline revenue requirement data (including operating budget, rate of return, depreciation assumptions, etc.) are identical to those developed for all other wholesale customers.
- KWA is allocated Lake Huron Plant capital revenue requirements based on the proportion of their contracted max day demand (assumed in these calculations at 40.6 mgd) relative to the total capacity at the Lake Huron Plant (400 mgd). The resulting revenue requirements are recovered through a fixed monthly charge.
- KWA is allocated Lake Huron Plant operating revenue requirements based on the proportion of their contracted average daily usage (assumed in these calculations at 24 mgd) relative to the total average daily usage at the Lake Huron Plant (assumed at 125 mgd in these calculations).
- Calculations are conducted for two alternatives. Purchase of *pressurized* water (after high lift pumping) and *unpressurized* water (KWA takes directly from clearwell.)
- Contract includes an arrangement for emergency service at the existing Baxter / Potter connection, and computes a standby charge related to such service.
- The standby charge is computed in the manner set for the by the American Water Works Association (AWWA) in its Manual of Water Supply Practices M1 - "Principles of Water Rates, Fees, and Charges" Manual M1.
    - KWA is allocated one day's worth of transmission related capital revenue requirements.

Scenario 2 – "Full Service" Lake Huron System

- Same as the "pressurized" option in Scenario 1, except that concept is extended to the pumping, storage, and transmission facilities directly served by the Lake Huron Plant
- Transmission rate schedule is computed based on specific costs associated with these facilities. No other DWSD revenue requirements, including those associated with other DWSD transmission mains, etc, are included in the rate to KWA.
- Revenue requirements are separated into capital recovery and operation and maintenance expense elements. Baseline revenue requirement data (including operating budget, rate of return, depreciation assumptions, etc.) are identical to those developed for all other wholesale customers.
- KWA is allocated Lake Huron "transmission system" capital revenue requirements based on the proportion of their contracted max day demand (assumed in these calculations at 40.6 mgd) relative to the total capacity at the Lake Huron Plant (400 mgd). The resulting revenue requirements are recovered through a fixed monthly charge.

- KWA is allocated Lake Huron "transmission system" operating revenue requirements based on the proportion of their contracted average daily usage (assumed in these calculations at 24 mgd) relative to the total average daily usage at the Lake Huron Plant (assumed at 125 mgd in these calculations).
- Standby charge is eliminated.

The resulting potential proposed rate structures under both Scenarios are summarized below.

Potential Proposed DWSD Water Rate to KWA
Lake Huron Direct Scenario

	1 - Supply Rate @ LH Plant		2 - Full Service
	Unpressurized	Pressurized	Wholesale Rate
Supply Rate			
Fixed Monthly Capital Charge - $	219,900	316,600	503,200

Total Average Unit Cost - $/Mcf	*6.57*	*8.53*	*10.46*

180 M.11 over 30 yrs
503 M x 360 mo
= 180 M.11

The direct comparison over the period 2013-2042 is demonstrated in Attachment 2.

As KWA considers this proposal, I offer the following observations for consideration:

- The Public Partnership requires the least near term capital investment and preserves the economy of scale associated with operation of a large regional system resulting in an immediate reduction in the cost of water supply for Flint/Genesee, making the identified and necessary near term investment in local water infrastructure more feasible.
- The Public Partnership provides the opportunity to optimize service level and efficiency through collaborative asset management decision making.
- The Public Partnership provides representation for critical decision making consistent with DWSD newly demonstrated interest in engaging our customers in critical decisions impacting them. This formalizes that interest in contractual terms.
- The Public Partnership reduces the risks identified with a 'go alone' solution, including further declines in use/sales (see graph), project cost overruns or schedule delays and other unforeseen costs inherent in starting a new venture. See Attachment 3
- The DWSD Board of Commissioners has previously approved sale of raw water from the Lake Huron facilities for raw water end use. We remain open to further discussion about the raw water capacity needs and stand ready to provide an affordable commodity option.

$?
586 M.11
Attach. 1

DWSD is an organization in transformation. In April of 2011, a new Board of Commissioners was seated with additional autonomy and more direct customer representation. In the past year we have demonstrated the ability to reduce costs, resolve long standing compliance issues and have gained support for establishing a new legal and operational model for DWSD that could enable broadened representation for Flint/Genesee on the Governing Board.

I remain available to discuss this proposal to assure that each of the issues critical to Flint/Genesee are addressed.

Best regards,

Sue McCormick, Director
Detroit Water and Sewerage Department

Cc: Andy Dillon, State Treasurer
Dayne Walling, Mayor – City of Flint
Kevyn Orr, City of Detroit Emergency Financial Manager
Jeff Wright, Genesee County Drain Commissioner
James Fausone, Chair – Detroit Board of Water Commissioners

— Press Conf. @ 4:30 PM

City of Flint

Public Forum

Wednesday January 21, 2015
7:00 pm City Hall Dome

AGENDA

Opening COF – DPW Director - Howard Croft

- Forum Ground Rules (disorderly conduct will not be tolerated)
- Overview of Format (each guest to speak for ~10 minutes with written questions afterword)
- Recognition of Officials
- Introduction of Guests

1st Speaker DEQ – Local Representatives - Mike Prysby, Steve Busch

- Role of DEQ
- Explanation of TTHM violation

2nd Speaker LAN – Lead Engineer - Warren Green

- Discuss Engineering role
- Discuss Operational Evaluation Report

3rd Speaker MSU Microbiologist – Dr. Joan Rose

- Risk Assessment (what do the numbers mean?)
- What to do if someone suspects they are at risk
- What about the elderly and those with a weak immune system
- What will the next violation mean (water is still safe)

4th Speaker GCDC – Jeff Wright

- What to expect from KWA raw water as source
- Update on KWA timeline

Final COF – DPW Director – Howard Croft

- Summary (Next Steps – Action Plans)
  - Hiring an industry expert
  - Tours of Treatment Plant
  - Continued communication
  - Planned steps (CIP built on , Water Reliability Study, Operational Evaluation Report)
  - Funding (researching all sources, state funding, federal opportunities)
  - Water & sewer rates (budgetary evaluation upcoming)
- Questions (Expected to have an hour of panel response time)
- Conclusion - Thank the panel, (Additional follow up at next Public Works Committee meeting)

Department of Environmental Quality (DEQ)

Michael Prysby, P.E.
District Engineer

Stephen Busch, P.E.
Lansing and Jackson District Supervisor

Lockwood, Andrews, and Newnam (LAN)

J. Warren Green, PE
Senior Associate, Director of Engineering

Warren has more than 30 years of experience in engineering management and supervision of complex water treatment and transmission facilities projects. He has successfully guided water system improvements through all necessary phases including feasibility studies, pilot testing, design, financial evaluation, land acquisition, construction, start-up and operation. His expertise is in the areas of facilities design, construction management and contract administration.

He has worked with several municipal utility clients throughout Illinois, Mississippi, Michigan and Wisconsin. He worked with the Green Bay Water Utility in Green Bay, Wis., for 12 years, serving as a project manager for a number of design and contract administration tasks. These included the expansion of a 10-mgd raw water pumping station, construction of approximately 17 miles of 54-in. steel water transmission main, and expansion of its water treatment plant in 1997 and 2004. He also oversaw a $376 million project in DuPage County, Ill., where he was responsible for contract administration and construction management of 140 miles of water transmission mains.

MSU Water Quality and Environmental Microbiology Laboratory

Dr. Joan B. Rose, Ph.D.
Laboratory Director/Principal Investigator
Homer Nowlin Chair in Water Research
Co-Director Center for Water Sciences
Co-Director Center for Advancing Microbial Risk Assessment

Joan is an international expert in water microbiology, water quality and public health safety and is a member of the National Academy of Engineering. She has been involved in the investigation of numerous waterborne outbreaks world-wide. Her work addresses the use of new tools for surveying and mapping water pollution for recreational and drinking water; assessment of water treatment technology and use of risk assessment.

Degrees:

- Bachelor's (1976) and Ph.D. (1985), microbiology, University of Arizona
- Master's (1980) microbiology, University of Wyoming

Genesee County Drain Commissioner

Jeff Wright

Past positions include:

- Chief Executive Officer of Karegnondi Water Authority
- Legislative Committee and Executive Board of Michigan Association of County Drain Commissioners
- Northeast District Chairman – Michigan Association of County Drain Commissioners
- Former Secretary/Treasurer – Michigan Association of County Drain Commissioners

CITY OF FLINT

Dayne Walling
Mayor

January 18, 2015

The Honorable Rick Snyder
Governor, State of Michigan
P.O. Box 30013
Lansing, MI 48909

RE: Flint Water Improvement Plan

Dear Governor Snyder:

On behalf of the Flint community, I am writing to convey serious concerns about water quality and to request your support for my proposed Flint Water Improvement Plan. Access to safe and clean water is a basic human right, and, therefore, policy and budget decisions need to ensure that water is affordable and secure for everyone in Flint and all across Michigan It is essential there is City, State and Federal cooperation to address the challenges here and to meet the needs of vulnerable populations.

The Flint Water Improvement Plan is focused in five areas: safety, quality, access, investment and education. The plan puts safety and quality first because this is fundamental. It is designed to be a sustainable solution for the City of Flint and the community as we move towards a new permanent water supply from Lake Huron through the Karegnondi Water Authority. My plan offers new ideas and also builds on successful models of utility, energy and assistance programs at the State and Federal levels.

Safety & Quality

- 100% Safety is the standard
- City of Flint reports testing data to the public to assure safety and expands testing sites and frequency
- Bring on experienced river water treatment operational management in the City of Flint

Access

- Announce an amnesty program for Flint water service turn-ons and reduce the turn-on fee
- Develop a revised affordable payment plan policy to encourage customers to return
- Design Federal and State partnership to establish new Drinking Water Emergency Assistance Fund for the elderly and vulnerable families

Investment

- Accelerate water system improvements outlined in the City of Flint Capital Improvement Plan through Federal and State Investments
    - State approves City of Flint's Distressed Cities Fund applications

- Federal and State support for replacement or forgiveness of payment to the Drinking Water Revolving Loan Fund due to Flint's status as a distressed community
- Federal and State grants for infrastructure improvements in alignment with the Flint Master Plan

- City Water Department implements budgeted FY15 projects including leak detection, valve repairs, new pipes and meter replacements

Education

- Develop a community partnership with universities to provide household and business customers with information on testing and conservation
- Ongoing partnership with Michigan Department of Human Services, United Way, Salvation Army and community organizations to provide information and water assistance with the Keep the Water Flowing Fund and support services
- Expand youth energy initiative to assist households with conservation and efficiency (piloted in summer 2014 with Northwestern High School students, EcoWorks and Consumers Energy)

It is also critical to restore the public confidence in Flint Water. The implementation of this plan must be accompanied by extensive community engagement including local elected officials. My objective is to work with you and your appointed officials, State Senator Ananich, State Representatives Phelps and Neeley, Congressman Kildee, community groups, businesses, churches, foundations, the Flint City Council, and all of the City of Flint and government personnel.

It is imperative that we communicate better and provide residents more information. I understand representatives from the Michigan Department of Environmental Quality will be joining a public forum this week at City Hall. This engagement going forward is vital so thank you for supporting their efforts. I think this issue of transparency is important for communities all across the State. I recommend a review of the applicable laws and policies and, at a minimum, a new requirement that water testing data be reported publicly no less than quarterly by law in all Michigan communities in Flint's population category.

Thank you for the consideration Governor. There is nothing more important in Flint right now than fixing the water problems. We must work together to identify funds to repair and update the water treatment facilities and city-wide infrastructure and to help those persons without access to clean water so that the entire Flint community has sustainable, safe, secure and affordable water now and into the future. This is an important issue for the state of our State of Michigan and I urge you to work with us to implement solutions.

Sincerely,

Dayne Walling, Mayor
City of Flint

CC: Flint City Council President Joshua Freeman; Congressman Dan Kildee; State Senator Jim Ananich; State Representative Sheldon Neeley; State Representative Phil Phelps; Flint Emergency Manager Jerry Ambrose

89 (Rev. 02-11)

STATE OF MICHIGAN
DEPARTMENT OF TREASURY
LANSING

RICK SNYDER
GOVERNOR

ANDY DILLON
STATE TREASURER

Mr. Edward Kurtz
Emergency Manager
City of Flint
1101 South Saginaw Street
Flint, MI 48502

April 11, 2013

Dear Mr. Kurtz:

Thank you for your March 29, 2013 letter, which is attached for reference. As the Emergency Manager for the City of Flint ("Flint" or "City"), you have asked for my concurrence, pursuant to Public Act 436 of 2012, the Local Financial Stability and Choice Act, to authorize a contract in excess of $50,000.00 not subject to competitive bidding. This request was related to the City entering into an agreement with the Karegnondi Water Authority (KWA) for provision of raw water for the City.

In considering your request, I took note of the following facts in support of Flint joining KWA. First, there is widespread support in the City for this move, including the support of the Mayor, the City Council, and the Emergency Manager. Second, this move will provide a unique opportunity for the City and County to partner on an important project, which will hopefully lead to future regional collaboration. Third, the Department of Environmental Quality is supportive of the City participating in the KWA project. Finally, your representations that this deal will lead to substantial savings for the City over the coming decades, savings that are desperately needed to help with the turnaround of the City of Flint.

It is my understanding that the Detroit Water and Sewer Department is making a final best offer to Genesee County and the City of Flint next Monday, April 15, 2013. As such, this approval will be effective at 5 pm on April 16, 2013 after receiving written notice from the City that either no such offer was presented to the county and the City or that an offer was received and was rejected in good faith based upon specified objections.

For the reasons described above and subject to the conditions set forth herein, pursuant to Section 12 (3) of PA 436 of 2012, I am authorizing you to proceed with adopting the resolution and entering into a contract with KWA.

Sincerely,

Andy Dillon
State Treasurer

EPA

Understanding End Water Quality in Hospitals and Other Large Buildings

A certificate for one continuing education contact hour will be offered for this webinar

Tuesday, April 28, 2015
2:00 to 3:00 pm EST

Use and effectiveness of various available technologies for the treatment and control of *Legionella*

The presentation will provide a brief overview on the EPA draft document "*Legionella*: Current Knowledge on Treatment Technologies" which will characterize the current body of knowledge regarding the use and effectiveness of various available technologies for the treatment and control of *Legionella*. The document will provide an overview on *Legionella*'s microbial, epidemiological and other characteristics as well as describe various control approaches for the prevention and remediation of *Legionella*. The information on treatment technologies will include a characterization of their effectiveness, water quality issues and recommended operational conditions based on the reviewed literature. The document could assist primacy agencies, affected facilities and system operators in their decision-making process regarding measures to control for *Legionella* in building water systems.

Presented by César Cordero – *EPA's Office of Water.* César joined the Standards and Risk Reduction Branch (SRRB) of the EPA Office of Ground Water and Drinking Water (OGWDW) in 2007. During his time in SRRB he has been involved in the review of the Revised Total Coliform Rule and the Long Term 2 Enhanced Surface Water Treatment Rule. He has also been involved in the development of the Contaminant Candidate Lists as well as helping address issues related to emerging waterborne pathogens. César has a B.S. in Industrial Microbiology and an M.S. in Biology, both from the University of Puerto Rico-Mayaguez.

Water quality issues in large buildings and emerging treatment technologies for premise plumbing-related pathogens

The Safe Drinking Water Act (SDWA) sets limits on water quality indicators for water in the distribution system. Once this distributed water enters a building or household, the responsibility of maintaining water quality shifts to the owners. The latest data for waterborne diseases indicates that premise plumbing-related outbreaks are increasing across the U.S. This fact, and the legal ramifications of waterborne outbreaks, are leading hospital and hotel owners to address water quality in their buildings. This presentation will discuss ORD's investigation of water quality issues in large buildings, with the goal of providing information to building owners on how water quality changes as it moves through complex premise plumbing systems. The evaluation of emerging treatment technologies designed specifically to control premise plumbing-related microbial pathogens will also be discussed.

Presented by Mark Rodgers, Ph.D. – *EPA's Office of Research and Development.* Mark Rodgers is the Chief of the Microbial Contaminants Control Branch, in the EPA National Risk Management Research Laboratory. In this role he supervises microbiologists working on a diverse research program that includes the development of assays for determining sources of fecal contamination in source waters, the community composition of biofilms in drinking water distribution systems, the fate of pathogenic and indicator organisms in biosolids and the effectiveness of various conventional and emerging drinking water disinfectants.

Cc: Lee, Lonnie (DEQ); Browne, Elizabeth (DEQ); Hoffman, Kelly (DEQ); Willard, Veronica (DEQ); Ashford, Stephen (DEQ); Prysby, Mike (DEQ)

Subject: RE: Genesee County - Proposal for regional system

In the original meetings, we agreed that the Saginaw Bay District would review the plans for the intake, raw water pump station and the transmission line through Sanilac County. The Lansing District was responsible for the raw water transmission line through Lapeer and Genesee Counties plus the treatment plant located in Genesee County. John O'Brien et al, from Genesee County Drain Commission, participated in these meetings.

We have all ready reviewed portions of the draft feasibility study and conceptional plans.

Subject: Genesee County - Proposal for regional system

Just wanted to follow-up a meeting we (Sonya Butler, Kelly Hoffman, and I) sat in on last week with Genesee County to discuss the new water authority and their plans for a regional system with Lapeer County, Sanilac County, the city of Lapeer, and the city of Flint.

In general, they took the opportunity to describe for us their master plan. We discussed options for revolving loan dollars. In addition, they asked if we (the community water supply program) could coordinate the reviews for permitting that would be needed in light of the fact that the project will be crossing district boundaries.

I think it will be helpful if we could discuss via a conference call. Since everyone was out last week at the Section meeting, I haven't had a chance to coordinate the conversation yet. Thought I'd share this note to get you thinking about issues you might see on the horizon.

Laura – I've included you since the Detroit system is obviously impacted by any proposal that is being discussed. They indicated in the meeting that they had reached an agreement (or at least a meeting of the minds) with the city of Detroit regarding a couple of options available to them relative to proceeding with the proposal. Perhaps you've heard something from the city that might shed some more light on this.

Veronica could you please set up a call for us. Friday morning looks good for me. It might have to wait until next week depending on calendars.

Kelly – would it be helpful for you to participate in the call in order to hear the discussion from the program side? They may also have questions for you.

FLINT, MI -- The Flint City Council declined to take action on whether the city should participate in the construction of a multi-county pipeline that would bring drinking water to the city from Lake Huron.

Guests get a look at the sedimentation process at the Flint Water Treatment Plant during a tour of the plant as a way to educate the public on the process of the water treatment. The plant is run four times a year to make sure it's working correctly. The plant would filter Lake

File Photo

Council members voted 6-3 Monday, March 11, to delay the decision on joining the **Karegnondi Water Authority (http://www.mlive.com/news/flint/index.ssf/2010/10/karegnondi_water_authority_set.html** which would pull water from Lake Huron and replace the city's reliance on Detroit for water.

Council members Dale Weighill and Joshua Freeman, as well as council President Scott Kincaid, voted against the delay. Kincaid cited the possibility of a new emergency financial manager being appointed by Gov. Rick Snyder in Detroit later this week as a reason why the council should make the decision

Currently, the city obtains its drinking water from the Detroit-operated water system but rising costs have left the city seeking new sources.

Flint emergency financial manager Ed Kurtz has **still not recommended (http://www.mlive.com/news/flint/index.ssf/2013/01/future_flint_water_rates_still.html)** to the state whether the city would join the authority.

However, Mayor Dayne Walling said the council has the authority to make the decision on joining the authority after voters repealed the previous emergency manager law in 2012.

- Bay City
- Detroit
- Flint
- Grand Rapids
- Jackson
- Kalamazoo
- Lansing
- Muskegon
- Saginaw
- All Michigan

Walling said the needed to make a decision on joining the authority before the state makes a decision on the city's behalf and a revamped emergency manager law goes into effect at the end of the month.

"We've determined there was a window of opportunity here for this body to take its rightful role ...," said Walling. "It's likely we could wake up tomorrow and the state could take us in a different approach."

City attorney Pete Bade said that he believes Kurtz would retain the final decision on the future of the city's drinking water but added that a council decision could still be influential in the process.

Sign in

"I wouldn't look at the resolution as a shallow piece of paper," said Bade.

Kurtz could decide to go along with the council's decision or veto it and institute his own plan.

The Karegnondi proposal calls for the city to purchase 18 million gallons of untreated Lake Huron water daily through the pipeline. The water would be treated at the city's treatment plant and then distributed to Flint customers.

Genesee County Drain Commissioner Jeff Wright, who addressed the council Monday night, said the city would pay roughly $6.4 million annually for water service if it joined the pipeline -- a nearly $4 million savings on what it pays Detroit for water.

Wright said the rate would be fixed over a 25-year period, whereas what Detroit charges is likely to continue increasing.

However, some council members were concerned about why the proposal was just now being brought in front of the council when voters elected to repeal the previous emergency manager law months ago.

"I want to do what's best for the city of Flint," said Councilman Bernard Lawler, who voted to delay the decision.

Lawler said that he wasn't even given a weekend's notification to evaluate the proposal.

Councilman Sheldon Neeley, who also voted to delay the decision, agreed with Lawler and asked that the council have more time to evaluate the information.

But Wright cautioned the city against waiting too long. The drain commissioner said work is **slated to begin (http://www.mlive.com/news/flint/index.ssf/2012/10/construction_permit_approved_s.html** on the pipeline with or without Flint and if the city waits too long to join it could force costly redesigns.

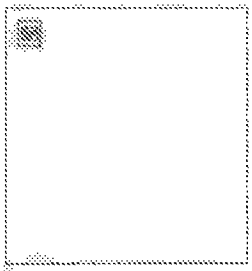
Wright said that a week delay should not affect Flint's costs but further delay could, as the construction season will soon be getting underway.

County commissioners have also **expressed their displeasure (http://www.mlive.com/news/flint/index.ssf/2013/02/genesee_county_commissioners_t_10.** with Flint over its pipeline decision.

The city, if it agrees to join the authority, would still rely on Detroit water for the roughly three years it will take to build the pipeline.

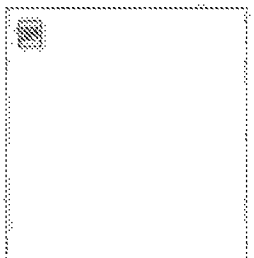
Flint finance director Jerry Ambrose said the city would likely experience a $20 million savings by 2020 if it joined the authority.

But Ambrose said it isn't clear if the savings would translate to lower rater rates or just slow down rate increases.



The city has raised its average water and sewer rates more than 110 percent since January 2011. City officials said the increases are due to rising legacy costs, population loss, rate increases from Detroit Water and Sewerage and maintenance of an aging system.

"It's not realistic to say, based on this, that we'll see a reduction in rates," said Ambrose.



The council is now scheduled to vote on the proposal March 18.

Detail of Worse Case Cost Projections

Worse Case Scenerio

Cost Comparisons: Water Supply to City of Flint from DWSD and proposed KWA project

Cost of Water to City of Flint (excluding Genesee) using continued service from DWSD

	FY13	FY14	FY15	FY16	FY17	FY18	FY19	FY20
Fixed Cost (1)	$ 4,411,680	$ 4,852,848	$ 5,338,133	$ 5,871,946	$ 6,459,141	$ 7,105,055	$ 7,815,560	$ 8,597,116
Escalator	1.1	1.10	1.10	1.10	1.10	1.10	1.10	
Commodity Cost (2)	$ 7,276,640	$ 7,640,472	$ 8,022,496	$ 8,423,620	$ 8,844,801	$ 9,287,041	$ 9,751,394	$ 10,238,963
Escalator	1.05	1.05	1.05	1.05	1.05	1.05	1.05	
Flint WTP Operating Cost (3)	$ 2,725,538	$ 2,861,815	$ 3,004,906	$ 3,155,151	$ 3,312,908	$ 3,478,554	$ 3,652,482	$ 3,835,106
Escalator	1.05	1.05	1.05	1.05	1.05	1.05	1.05	
TOTAL	$14,413,858	$ 15,355,135	$16,365,534	$17,450,717	$ 18,616,851	$19,870,650	$ 21,219,436	$ 22,671,185

(1) Per FY13 Budget and DWSD Contract, fixed charge from DWSD for FY13 is $707,000 per month or $8.5 million total. Flint's cost is 52% or $4.4 million total.

(2) Per FY13 Budget and DWSD Contract, and based on 12 million gallons per day (mgd), cost is $7.3 million, based on $12.46/unit ($12.46x1600unitsx365).

(3) Per FY13 Budget, annual cost of WTP is $4.1 million. Genesee County pays $1,386,000 for emergency back up service.

Cost of Water to City of Flint using proposed KWA project for water supply to Flint WTP

	FY13	FY14	FY15	FY16	FY17	FY18	FY19	FY20
KWA Entry Costs (1)	$ 581,400	$ 581,400	$ 581,400	$ -	$ -	$ -	$ -	$ -
Fixed KWA Construction Cost (2)				$ 7,582,128	$ 7,582,128	$ 7,582,128	$ 7,582,128	$ 7,582,128
Escalator						1.00	1.00	
Fixed Flint WTP Construction Cost (3)				$ 556,651	$ 556,651	$ 556,651	$ 556,651	$ 556,651
Escalator								
Flint WTP Operating Cost (4)	$ 5,911,538	$ 6,207,115	$ 6,517,471	$ 6,843,344	$ 7,185,511	$ 7,544,787	$ 7,922,026	$ 8,318,128
Escalator	1.05	1.05	1.05	1.05	1.05	1.05	1.05	
KWA Commodity Charge (5)	$ 759,200	$ 797,160	$ 837,018	$ 878,869	$ 922,812	$ 968,953	$ 1,017,401	$ 1,068,271
Escalator	1.05	1.05	1.05	1.05	1.05	1.05	1.05	
TOTAL	KWA NOT AVAILABLE				$ 16,247,103	$16,652,519	$ 17,078,206	$ 17,525,177

(1) The City will, upon joining, be required to pay a fee of $32,300 per MGD for each year until bonding for the project is obtained. At 18MGD, the City's cost is $581,000 annually. It is projected that fee will be assessed for 3 years.

(2) Per KWA proposal, project cost is $272 million. City's fixed cost would be 30% of debt service, based on capacity design of 60mgd, of which 18MGD is for Flint. Debt service is based on 5% interest rate @ 25 years; 5% added to principal for capitalized interest for FY13, FY14, and FY15. ($272,421,588 plus $13,621,078 for 3 years = $313,284,792). **The costs here are increased by 15%; debt service starts in FY16 but water is not available until FY17.**

(3) Per KWA proposal, the cost of upgrading the Flint is $6 million. City's fixed cost would be100% of debt service based on 5% interest rate @ 25 years), with 5% added to cover capitalized interest for FY13, FY14, and FY15, (total principal = $6.9 million). **Again. costs here are increased by 15%; debt service starts in FY16 but water is not available until FY17.**

(4) Per FY13 Budget annual cost of WTP is $4,111,538. $1.6 million for electricity and chemicals & 2 FTE's are added. 100%

(5) Per KWA proposal, initial commodity charge would be based on $1.30/unit or 7,500 gallons. Charge is based on 12MGD.

11/1/12

WORSE CASE SCENARIO
SUMMARY COMPARISON: KWA V DWSD
(15% Cost Overrun; One year delay in Water Supply delivery)

Water and Sewer Cash Flow with KWA

	Year 1 FY13	Year 2 FY14	Year 3 FY15	Year 4 FY16	Year 5 FY17	Year 6 FY18	Year 7 FY19	Year 8 FY20
Current DWSD & FWTP Costs	$14,413,858	$ 15,355,135	$16,365,534	$17,450,717	$ -	$ -	$ -	$ -
KWA Entry Fee	$ 581,400	$ 581,400	$ 581,400	$ -	$ -	$ -	$ -	$ -
KWA Debt	$ -	$ -	$ -	$ 7,582,128	$ 7,582,128	$ 7,582,128	$ 7,582,128	$ 7,582,128
FWTP Debt	$ -	$ -	$ -	$ 556,651	$ 556,651	$ 556,651	$ 556,651	$ 556,651
KWA operations	$ -	$ -	$ -	$ -	$ 922,812	$ 968,953	$ 1,017,401	$ 1,068,271
FWTP operations w KWA	$ -	$ -	$ -	$ -	$ 7,185,511	$ 7,544,787	$ 7,922,026	$ 8,318,128
TOTAL COSTS	$14,995,258	$ 15,936,535	$16,946,934	$25,589,496	$ 16,247,103	$16,652,519	$ 17,078,206	$ 17,525,177

Water and Sewer Cash Flow with DWSD

	Year 1 FY13	Year 2 FY14	Year 3 FY15	Year 4 FY16	Year 5 FY17	Year 6 FY18	Year 7 FY19	Year 8 FY20
Current DWSD & FWTP Costs	$14,413,858	$ 15,355,135	$16,365,534	$17,450,717	$ 18,616,851	$19,870,650	$ 21,219,435	$ 22,671,185

Cash Flow Difference: KWA and DWSD

	Year 1 FY13	Year 2 FY14	Year 3 FY15	Year 4 FY16	Year 5 FY17	Year 6 FY18	Year 7 FY19	Year 8 FY20
Annual KWA - DWSD	$ (581,400)	$ (581,400)	$ (581,400)	$ (8,138,779)	$ 2,369,748	$ 3,218,131	$ 4,141,229	$ 5,146,008
Cumulative	$ (581,400)	$ (1,162,800)	$ (1,744,200)	$ (9,882,979)	$ (7,513,231)	$ (4,295,100)	$ (153,871)	$ 4,992,137

"Worse Case" scenario differs from Original in these respects:

Delivery of water to Flint from KWA is delayed by one year and construction costs are 15% above the origin projection.

(1) Consequently, the City is required to begin paying for debt service one year before KWA begins delivery of water. This is in addition to its obligation to pay its entry fee of $581,000 annually for the first 3 years.

(2) Considering $9.8 million in upfront costs in the first 4 years prior to KWA operation, the cost of KWA exceeds the cost of DWSD until year 8. Once KWA begins delivering water in year 5, annual operating costs are less than DWSD by 13%

(3) Cumulative savings by Year 8 are projected to be $5 million, compared to $24 million in the Original projection.

Subject: Karegnodi Water Authority (Genesee County Drain Commission) Intake

Near final plans for the Karegnodi Water Authority's proposed intake will be submitted to the SBD Office within the next few days. It is our understanding that Water Resources does not have any issues with the minor changes in the intake's exact location. Also, it is our understanding that Water Resources will be placing the project out for public comment with a proposed closing date of July 18th.

Prior to the July 18th closing date, the SBD Office staff will meet with the consultants to discuss the plans. If the plans do meet the minimum requirements for the SDWA, it is my intentions to issue the construction permit immediately on the determination that the requirements have been met. The issuance of the permit under the SDWA will not obviate the necessity of the authority for obtaining any other permits or approvals.

Hello Mr. Busch,

If possible would you or a representative from your office please attend the conference call that is being hosted by MDCH regarding the Legionella cases in Genesee County. Your knowledge and experiences may help us better understand the Flint municipal water system and municipal water in general, relative to Legionella. I understand that this is short notice, the meeting is today at 2:30pm and the call line is below.

RE: Flint Municipal Water Information Request

Dear FOIA Coordinator,

Under provisions of the Michigan Freedom of Information Act (MCLA 15.231 et seq; MSA 4.1801 (1) et seq) please provide the following:

Please provide the dates and specific locations of the water main breaks for 2014. Please provide an electronic version with the address data file, if possible.

Please provide dates and specific locations of flushing activities within a mile radius around McLaren Hospital, Flint for 2014

Please provide a copy of the Veolia presentation that was displayed at the Technical Advisory Committee on March 4, 2015. If possible please provide an electronic version.

Please provide the monitoring locations and results for heterotrophic bacteria for 2013 through 2014.

If you determine that any of the requested information is exempt from disclosure, please detail what is being withheld and cite the exemption under FOIA. I anticipate the request being filled within five working days of receipt of this letter, as provided under FOIA. Please contact me at (810) 257-3618 if there are fees associated to comply with this request.

Sincerely,

In Asia: As of December 31, 2010, research analysts at Standard & Poor's Equity Research Services Asia have recommended 39.4% of issuers with buy recommendations, 51.8% with hold recommendations and 8.8% with sell recommendations.

Globally: As of December 31, 2010, research analysts at Standard & Poor's Equity Research Services globally have recommended 35.2% of issuers with buy recommendations, 54.0% with hold recommendations and 10.8% with sell recommendations.

★★★★★ **5-STARS (Strong Buy):** Total return is expected to outperform the total return of a relevant benchmark, by a wide margin over the coming 12 months, with shares rising in price on an absolute basis.

★★★★ **4-STARS (Buy):** Total return is expected to outperform the total return of a relevant benchmark over the coming 12 months, with shares rising in price on an absolute basis.

★★★ **3-STARS (Hold):** Total return is expected to closely approximate the total return of a relevant benchmark over the coming 12 months, with shares generally rising in price on an absolute basis.

★★ **2-STARS (Sell):** Total return is expected to underperform the total return of a relevant benchmark over the coming 12 months, and the share price not anticipated to show a gain.

★ **1-STARS (Strong Sell):** Total return is expected to underperform the total return of a relevant benchmark by a wide margin over the coming 12 months, with shares falling in price on an absolute basis.

Relevant Benchmarks: In North America the relevant benchmark is the S&P 500 Index, in Europe and in Asia, the relevant benchmarks are generally the S&P Europe 350 Index and the S&P Asia 50 Index.

For All Regions: All of the views expressed in this research report accurately reflect the research analyst's personal views regarding any and all of the subject securities or issuers. No part of analyst compensation was, is, or will be directly or indirectly, related to the specific recommendations or views expressed in this research report.

Additional information is available upon request.

This report has been prepared and issued by Standard & Poor's and/or one of its affiliates. In the United States, research reports are prepared by Standard & Poor's Investment Advisory Services LLC ("SPIAS"). In the United States, research reports are issued by Standard & Poor's ("S&P"), in the United Kingdom by Standard & Poor's LLC ("S&P LLC"), which is authorized and regulated by the Financial Services Authority; in Hong Kong by Standard & Poor's LLC which is regulated by the Hong Kong Securities Futures Commission, in Singapore by Standard & Poor's LLC, which is regulated by the Monetary Authority of Singapore; in Japan by Standard & Poor's LLC, which is regulated by the Kanto Financial Bureau; in Malaysia by Standard & Poor's Malaysia Sdn Bhd ("S&PM") which is regulated by the Securities Commission and in Australia by Standard & Poor's Information Services (Australia) Pty Ltd ("SPIS") which is regulated by the Australian Securities & Investments Commission; and in Korea by SPIAS, which is also registered in Korea as a cross-border investment advisory company.

The research and analytical services performed by SPIAS, S&P LLC, S&PM, and SPIS are each conducted separately from any other analytical activity of Standard & Poor's.

Standard & Poor's or an affiliate may license certain intellectual property or provide pricing or other services to, or otherwise have a financial interest in, certain issuers of securities, including exchange-traded investments whose investment objective is to substantially replicate the returns of a proprietary Standard & Poor's index, such as the S&P 500. In cases where Standard & Poor's or an affiliate is paid fees that are tied to the amount of assets that are invested in the fund or the volume of trading activity in the fund, investment in the fund will generally result in Standard & Poor's or an affiliate earning compensation in addition to the subscription fees or other compensation for services rendered by Standard & Poor's. A reference to a particular investment or security by Standard & Poor's and one of its affiliates is not a recommendation to buy, sell, or hold such investment or security, nor is it considered to be investment advice.

Standard & Poor's and its affiliates provide a wide range of services to, or relating to, many organizations, including issuers of securities, investment advisers, broker-dealers, investment banks, other financial institutions and financial intermediaries, and accordingly may receive fees or other economic benefits from those organizations, including organizations whose securities or services they may recommend, rate, include in model portfolios, evaluate or otherwise address.

S&P and/or one of its affiliates has performed services for and received compensation from this company during the past twelve months.

MEMORANDUM
TO: Liane Shekter Smith, John O'Brien, and David Jansen
FROM: John C. O'Malia, P.E.
DATE: January 3, 2012
REF: KWA Status

It was good to talk to you regarding the status of KWA at the end of the year.
I am confirming our conversations as follows.

1. Mayor Walling, the incumbent, was re-elected. He is very much in favor of the KWA project and sits as Chairman of the KWA Board.

2. The Emergency Manager [EM], Mike Brown, was appointed by Governor Snyder. EM Brown formerly served as interim mayor of the City of Flint. He has expressed support for the KWA project.

3. EM has given powers back to Mayor and Council to make the decision on KWA as a precaution if the EM court challenge holds up. This will enable the Mayor and Council to approve the KWA agreement and not be challenged in court!

4. Expect Flint to approve KWA agreement January or February of 2012.

5. Would expect a meeting with MDEQ end of January or in February.

Will keep you posted on events as they develop. Look forward to working with you and staff. Happy New Year.

ROWE PROFESSIONAL SERVICES COMPANY

Large Firm Resources. Personal Attention.

January 7, 2013

Mr. Edward Kurtz, Emergency Financial Manager
City of Flint
1101 S. Saginaw Street
Flint, MI 48502

Subject: Review of December 21, 2012 Presentation – City of Flint Water Supply Assessment

Dear Mr. Kurtz:

As requested, we have reviewed the analysis of water supply alternatives for the City of Flint which was presented to the State Department of Treasury by Tucker, Young, Jackson, and Tull, Inc. (TYJT) on December 21, 2012. Our review is attached and summarizes the primary differences between the TYJT assessment and our previous studies and provides explanations of why we believe there are differences.

We have also reviewed the options for continued DWSD supply included in the TYJT presentation. It is not clear whether these are presented as specific offers on behalf of DWSD or included as examples for analysis, but we have noted some items which we believe should be addressed and considered as these options are compared.

If there are questions, please contact me.

Sincerely,
ROWE Professional Services Company

James E. Redding, P.E.
Vice President / Director of Engineering

Review of TYJT December 21, 2012 Presentation
City of Flint Water Supply Assessment
Prepared by Rowe Professional Services Company

DWSD Supply (Slides 7 through 9)

1. The 8 mgd maximum day supply by DWSD options can result in periods during the summer when most of the water to meet demands will be supplied by the City from the river. To aid in maintaining a consistent water quality, softening of the water from the river should be provided with this option, greatly increasing the City's costs.

2. Upgrades to Flint's WTP and dams will be needed for options requiring blending, since the WTP will be required to provide continuous, reliable service and compliance with recent surface water treatment regulations.

3. The rates for the options analyzed are shown on Slide 9 as "TYJT Estimates". Options and rates shown are different than presented by DWSD previously.

	DWSD 11/29/2012	TYJT Estimates
18 mgd Maximum Day - P&B	$16.24	$16.37
12 mgd Maximum Day - P&B	$16.30	$16.31
8 mgd Maximum Day -P&B		$12.68
12 mgd Maximum Day - Imlay	$14.38	$14.38
8 mgd Maximum Day - Imlay		$11.11

4. Since the rates used in the analyses are shown as estimates, are they actual offers or just presented as "what if" scenarios?

5. We assume that the Imlay options are based on transfer of the 72" main through Lapeer County to Flint. The analyses show a capital cost of $4.7 million; we assume that this is the proposed purchase / lease cost to Flint. This should be clarified along with pertinent details.

6. If the transmission main is transferred to Flint, what are Flint's responsibilities regarding service to the Lapeer County customers? If they remain DWSD customers, then Flint should receive some revenue for the use the main. It does not appear this is included in the TYJT analyses.

7. If the transmission main is transferred to Flint, we assume that the city will be responsible for the maintenance of the 50 year old main. The TYJT analysis did not include this.

8. Do the rates shown include the credit for "reliability" which had been discussed with DWSD?

9. If the point of commerce is changed from Baxter and Potter to Imlay, a new meter pit will be required. The cost of this does not appear to be included in the TYJT cost analyses.

Flint River Supply (Slide 10)

1. If any of the "blending" options are chosen, it will be necessary to upgrade the Flint WTP and dams to provide reliable, continuous service and compliance with recent surface water treatment regulations.

Data Collected (Slide 14)

1. The slide notes that Flint blending is based on DWSD supplying 2/3 and Flint supplying 1/3 of 12 MGD ADD. For the maximum day demand (18 mgd), if DWSD supplies a maximum of 8 mgd, Flint will supply 10 mgd or 56% of the total. However, such a large portion will make it more difficult to blend and achieve consistent water quality. Flint will need to soften water for these options.

Benchmarking Comparisons (Slide 16)

1. The slide subtitles are "KWA O&M Inflation Factor" and "DWSD and Flint Rate Inflation Factor". It seems appropriate to benchmark O&M costs for the KWA, because future costs of service will be dependent on how operating costs are impacted by inflation. For Flint, it does not seem appropriate that "rate inflation" from other utilities be used to determine the impact of inflation on future cost of service. Rates are impacted by inflation, but also by other factors such as debt and customer base. O&M expenses and rates are different and care should be exercised not to mix the two during analyses. The TYJT analyses apply an inflation factor (based on rates from other utilities) to the Flint WTP operating expenses, which does not seem to be consistent.

2. The KWA will supply raw water; SOCWA and YUCA both supply finished water. Regulations impact the O&M for finished water suppliers but should not impact the KWA O&M. The use of data from SOCWA and YUCA does not seem like a comparable comparison with the KWA. Finished water suppliers will have increased costs due to regulatory compliance, which really are not due to "inflation" of the costs of wages, power, chemicals, etc.

3. DWSD has a history of rates to Flint and other suburban wholesale customers. Rates tend to be quite specific to each utility, based on much more than just the costs of operating and maintenance. It appears that DWSD historical rates have not been considered in projecting future DWSD rate increases.

Capital Financing (Slide 17)

1. KWA bonds are planned to be general obligation bonds, backed by member counties.

O&M Inflation Factor (Slide 20)

1. SOCWA and YUCA are finished water suppliers; ever-changing regulatory requirements will impact their operating costs more than a raw water supplier, such as KWA.
2. KWA will be a supplier of raw water. O&M costs should primarily be limited to power and labor, with a little chemical use for zebra mussel control. KWA will not provide treatment of the water.

3. The KWA study assumed power, labor, and chemical costs increase at an annual average of 3%. TYJT indicated this is too low and suggested 5%.

4. Following are examples of historical inflation, which support the 3% as a reasonable assumption for O&M expenses (not rates)
    a. Labor- GCDC-WWS labor costs have increased at an annual average rate of 2.5% since 2003
    b. Electricity Rates in Michigan (per U.S. Energy Information Administration) have increased an average of 3.2% since 1999.
    c. The U.S. Bureau of Labor Statistics indicates that the inflation rate over the last 30 years has been an average of 2.8%.

Finished Water Rate Inflation (Slide 21)

1. TYJT bases their assumptions for rate inflation on a survey of rates from three other water suppliers, but ignored the actual rate history of DWSD. TYJT assumed DWSD rate increases of 4.4% annually (if water is purchased from P&B) and 2.9% annually (if water is purchased from Inlay). Based on the actual charges by DWSD to Flint, DWSD historical rates are as follows:
    a. 10 year increase in DWSD rates to Flint: 10.5% annually
    b. Average annual increase through 43 year history: 6.7%

2. Note that for the KWA analyses, an inflation factor has just been applied to power, labor, and chemicals. Although higher prices for labor, power, and chemicals impacts utility rates; rates are impacted by many other factors, many of which are not related to inflation. Rate inflation will likely be different than O&M inflation. Other factors impacting rates:
    a. Debt – the amount of debt varies widely between utilities
    b. Number of customers / quantity of water sold – there are many fixed expenses with a utility, that if are distributed amongst more users/more gallons sold will result in lower rates. Conversely, if there are fewer users or less water sold, the rates are higher. Assumptions regarding future water consumption will have a great impact on "rate inflation".

3. Unlike KWA and Flint operating expenses which will increase over time based on inflation, the cost of continued DWSD service should be based on the inflation of DWSD rates, to include the increasing cost of other DWSD expenses such as debt and the impact of reduced customers / demands in addition to increasing O&M expenses.

4. Even though there could be a one-time reduction in DWSD rates through adopting the model contract, limiting peak demands, and or changing the point of commerce; it doesn't seem reasonable to assume that subsequent annual increases will only average 4.4% through the 30 year period of analysis. This is significantly less than historical performance (yet TYJT suggests that inflation for KWA O&M expenses will increase at almost double the rate of historical indicators).

Capital Financing with Revenue Bonds (Slide 24)

1. Note that the KWA bonds will be general obligation bonds backed by the member counties.

2. The 2009 KWA Study assumed 6%, 25 year financing. The interest rate for planning was reduced in the 2012 Study update to 5%, which is still higher than if bonds were sold today.

3. Financial consultants determined the charges for purchasing capacity in the KWA supply based on the estimated project cost plus appropriate financing costs. Based on 60 units of capacity, $538,764,000 will be generated for repayment of debt and project costs using the capacity charges in the KWA capacity agreement.

25 years * 60 units * $355,300 / unit =	$532,950,000
3 years * 60 units * $32,300 / unit =	$ 5,814,000
	$538,764,000

4. For a KWA project cost of $272,421,558, total P&I is $483 million. The difference of $55,500,000 is available for financing expenses (capitalized interest, bond issuance costs, etc.) and additional contingencies.

5. Bond holder reserve is not a requirement for general obligation bonds.

6. TYJT assumed that 3% interest would be earned on the bond holder reserve during the 25 year bond period. Current interest rates are less than 1% and it seems inappropriate to assume such a high rate will be earned on retained funds.

7. Bondholder reserve, if provided, should be applied against the last couple of P&I payments. The TYJT did not apply it. This will reduce their project costs.

KWA Construction (Slides 26 through 29)

TYJT has indicated that the KWA construction cost estimate is too low. The primary differences in cost estimates for the project appear to be the following components:

1. Pump Stations (Slide 27) – The TYJT estimate for the pump stations is more than double that used by the KWA ($54,573,314 vs. $24,618,080). KWA estimates were based on actual construction costs from recent projectd completed by Genesee County within the last eight years.
   a. 32mgd water pump station including two-10 MG ground storage tanks - $13.4 million
   b. 80 mgd wastewater pump station, 50 feet deep wetwell – $8.3 million
   c. 30 mgd wastewater pump station, 50 feet deep wetwell – $9.4 million

   The KWA budgeted amount seems reasonable for two pumping stations as currently planned and to be constructed in rural areas (not southeast Michigan).

2. Redundant Power – There is no need for redundant power; other provisions will provide reliability of supply.

3. Land – Preliminary engineering has continued so earlier budgets established for planning for land acquisition can be greatly reduced. Options have been obtained on all properties which must be

purchased, so purchase prices are known. It will be necessary to obtain easements for only two miles of pipeline construction. All land costs are now estimated at $1.25 million.

4. Engineering, Legal, Administration & Contingencies
   a. The October 2012 KWA estimate provided an allowance of 25% of construction cost to cover engineering, legal, administration, and contingencies (ELAC). This was reduced from the 38% allowance used in the 2009 Study because ongoing planning and design have firmed up many of the details of the project, including:
      i. The intake design has been completed and all regulatory permits obtained.
      ii. The transmission main route has been determined. Meetings with road agencies have firmed up the requirements for construction and restoration within rights-of-way. Environmental review and permitting are in process.

   b. TYJT costs for Intake Crib, Pump Stations, and Transmission Mains (Slide 30) include a 30% allowance for ELAC. These allowances (from Slides 26 through 28) total $72,139,566. In addition, Slide 30 provides the following additional ELAC costs in the project total:

Design Engineering / Pump Stations	$16,939,581
Construction Management	$14,434,410
Administration	$ 349,440
Legal	$ 831,000
Total	$32,554,431

   c. Combining this with the $72,139,566 totals $104,693,997 or 43% of the estimated construction cost. We believe that such a high allowance for ELAC is not appropriate for a project of this magnitude where preliminary engineering and some design have already been completed.

Cost Comparison (Slide 30)

1. The TYJT pump station price is too high based on costs of similar projects; costs used by KWA are based on costs of recent local projects. The KWA estimate is believed to be sufficient for the proposed pumping stations.

2. Redundant power is not required; this does not need to be included in the TYJT estimate.

3. Land for LHPS – actual price is $360,000

4. Design Engineering / PS and Transmission – KWA included engineering in the 25% ELAC allowance included in the $207,752,895 estimated cost of transmission mains; TYJT included engineering in their 30% ELAC allowance included in the $218,811,559 estimated cost. By adding $16,939,581 for design engineering, $14,434,609 for construction administration, $349,440 for administration, and $831,000; it seems that ELAC is being "double-counted". The TYJT 43% allowance for ELAC seems unwarranted for a project with a great deal of preliminary and design engineering completed. The 25% KWA allowance is believed to be sufficient.

5. Easements and land (other than LHPS) should total $1,140,000, based on current options and specific needs for easements.

Other Considerations – Redundancy / Reliability (Slide 33)

1. Unfunded Mandates/ Future Regulations
    a. The proposed KWA supply will deliver raw water; it is not anticipated to be affected by future changes to regulations. Regulations will impact the City of Flint with respect to treatment and/or distribution of finished water. The City will be subject to these requirements with any of the DWSD blending options, just as they will be responsible for them if supplied by KWA. Some compliance costs may actually be less with the higher quality Lake Huron water rather than Flint River water as the source.

crypto & Cl in its on Flint River

2. State Goals
    a. The TYJT presentation indicates that creation of a new raw water supply is contrary to the governor's goals as suggested. However, the development of a new raw water supply provides new opportunities. Communities in Sanilac, St. Clair, and Lapeer counties will have the option to join a regional water supply and replace their small local supplies where limited supplies and high concentrations of arsenic have been a concern. The new water supply also provides great economic development opportunities. The raw water supplied by KWA will make a new commodity, raw water, available to the region. A large, low-cost supply of raw water can be a valuable resource for industries and agri-businesses. The development of a new water supply will also create construction jobs through the short term period of building the new water supply and subsequently over a longer period as new businesses and industries are developed in the area.
    b. The City of Flint and area communities will benefit as permanent jobs are created for operating and maintaining the local treatment facilities.

3. Redundancy
    a. We agree that the KWA and DWSD options are similar with respect to redundancy. Both provide the primary water supply; customers are responsible for their backup supply.

Other Considerations – Cost Slide 34

1. TYJT indicates that the DWSD 8 mgd supply option is the least cost alternative.
    a. The TYJT analysis does not include the cost of needed upgrades to the City's WTP or increased operating costs in their analysis. During summer months, water from the river will need to be softened before blending. More than half of the water supplied will be provided from the river. When the cost of upgrades to the WTP and the increased operating costs (for softening) are added to the TYJT analysis, the KWA option is less than the DWSD 8 mgd option.

2. For any of the DWSD "blending" options, upgrades will need to be made at the WTP to provide for continuous, reliable operation and compliance with new surface water treatment rules. Increased capital and operating costs for treating water from the river should be added to the TYJT costs for comparison with the other options.

3. Water from the river will require greater effort to treat than water from Lake Huron (more chemicals, power, and residuals). The TYJT analysis shows about the same O&M costs for the Flint WTP, regardless of water source. It seems that the WTP O&M costs for the KWA options should be reduced to reflect the savings from treating Lake Huron water.

4. The TYJT presentation noted that the KWA analysis did not include allowances for mechanical and process improvements within the planning period. The KWA will supply raw water. The facilities consist of pipe, pumps, and a tank. There are no treatment facilities which would be susceptible to future regulatory changes. The only improvements that seem likely would be the need to provide additional capacity. Capacity expansion is planned to be financed through capacity charges to new users.

5. The provision for redundant connections between the City's water system and the GCDC system was included in the most recent water supply agreement between the two, in 2011. Although not a KWA cost, the cost of the redundant connections should be considered with all options.

6. The $2.3 million budgeted for land by KWA was intended to cover all land requirements. Since the October update, options have been obtained on all land to be purchased and the locations of easements needed has been finalized. Total land costs are now estimated to be about $1.5 million.

7. The 2004 study included a 47% allowance for engineering, legal, administration, and contingencies (ELAC). The 2009 study reduced the allowance for ELAC to 37% because many of the details since the 2004 conceptual study had been better defined. For the October 2012 update, the allowance for ELAC was reduced to 25% because continued planning and preliminary engineering further addressed details from the earlier concepts.
    a. The detailed design (plans and specifications) and permitting have been completed.
    b. The transmission main route has been finalized. Meetings with road agencies have established requirements for construction and restoration within road rights-of-way. Environmental permitting is in process. The primary remaining unknown is pipe sizing, which is largely dependent on Flint's participation.

    It is our experience that the 25% ELAC allowance is appropriate for a project of this magnitude at this stage in the planning / design stage. The 43% ELAC allowance recommended by TYJT is excessive for a project in the design phase.

8. Flint's WTP as a backup to the KWA will be less difficult to provide for than the current arrangement as a backup to DWSD. We believe there is potential for challenges with chemistry and treatment for the proposed DWSD blending options, too.

9. It doesn't seem that oversizing the KWA capacity is a good solution for the city's water loss problems, if that is what is being suggested.

10. Yes, it would be nice if the KWA system could be constructed to firmly determine its cost and time to complete before making a decision about water supply alternatives. However, a decision is needed regarding Flint's participation so that the sizing and design can be completed, before it can be built.

Project Costs - TYJT Slides 26 through 30

	KWA	TYJT

For Immediate Release:

City of Flint Takes Proactive Measures to Improve Water Distribution System and Address Compliance Issues

Flint, Michigan – January 2, 2015 – The City of Flint's Department of Public Works has been actively working to address upgrades and repairs to the city's water distribution system. These actions appear to have corrected several long time concerns with the system as well as known compliance issues with the system, including a recent temporary increase in the maximum contamination level (MCL) of trihalomethanes (TTHM) found in water samples collected from the system during a testing period which ended November 30, 2014. The public was notified of the violation as a precautionary measure as required by the Michigan Department of Environmental Quality (MDEQ).

TTHM is a common by-product of the water chlorination process. Increased levels in some water samples collected in the city were an indicator of weaknesses in the distribution system and treatment process, which were due to years of deferred repairs and upgrades to a very old system. The City of Flint's DPW is and has been pursuing a comprehensive plan to make critical upgrades to its water distribution system for the long term health and operation of the system and to mitigate any future issues.

–CONTINUE–

CITY OF FLINT
OFFICE OF EMERGENCY MANAGER
DARNELL EARLEY
ICMA-CM, MPA

The levels of TTHM in the water were elevated marginally above the MCL in some samples, resulting in a less urgent "Tier 2" Environmental Protection Agency notification. This means that the EPA believes there is no immediate risk to consumers and/or the system may have already returned to acceptable levels by the time the notice was issued. Although TTHM is considered to be an environmental pollutant that can be carcinogenic, it can only be hazardous if consumed in water containing the elevated levels at a rate of two liters per person, per day for 70 years. The City of Flint wants to assure the public that according to the MDEQ the water is safe for drinking and all other purposes.

The City of Flint worked closely with the MDEQ to correct the issue by flushing hydrants and replacing key valves in the distribution system. These measures have shown to be effective in not only lowering the TTHM levels in the system, but have also improved the overall health of the system. The Michigan DEQ has acknowledged and appreciates the progress of the City's preemptive evaluation of operations which identified the deficiencies and the corrective measures being taken. The latest round of testing has shown a significant decrease in levels across the board, with most samples falling well below the MCL. It is expected that all sample levels will be well below the MCL in the next round of quarterly scheduled testing in March of 2015.

Flint's DPW welcomes the rigorous review of the MDEQ to ensure steady progress is made on this important issue. "Our proactive plan of replacing valves, flushing hydrants and making other adjustments to the system has shown both promising short term

–CONTINUE–

results as well as strengthening our water distribution capability in the long term," said Flint DPW Director Howard Croft. Both the City of Flint and the MDEQ expect the corrective measures being implemented will resolve the issue by early 2015.

The improvements in MCL levels also mirror the increased consistency being seen in chlorine residuals, flow rates, and overall water quality within the city. As part of the DPW strategic plan and Capital Improvement Plan, there are additional improvements coming to the 600 miles of distribution main including, pipe replacements, leak detection, hydraulic modeling, and enhanced asset management features. The Department of Public Works will continue to provide public education and communication about the quality, the process, and the continual improvements occurring within the system as part of the overall management of the water system.

–END–

IMPORTANT INFORMATION ABOUT YOUR DRINKING WATER

City of Flint Did Not Meet Treatment Requirements

Our water system was recently found to be in violation of a drinking water standard. Although this incident was not an emergency, as our customers, you have a right to know what happened and what we are doing to correct this situation.

We routinely monitor for the presence of drinking water contaminants. Samples were collected for total trihalomethanes (TTHM) analysis from eight locations on a quarterly basis (May 21, August 21, and November 20 of 2014). The average of the results at **ANY** of the eight locations must not exceed the maximum contaminant level (MCL) for TTHMs, otherwise our water system exceeds the Maximum Contaminant Level (MCL). The standard for TTHMs is 80 ug/L. The location reporting the highest TTHM level was 93 ug/L, thus, our water system exceeds the TTHM MCL.

What should I do?

- There is nothing you need to do unless you have a severely compromised immune system, have an infant, or are elderly. In that case, you may be at increased risk and should seek advice about drinking water from your health care provider.
- You do not need to boil your water or take other corrective actions. If a situation arises where the water is no longer safe to drink, you will be notified within 24 hours.

What does this mean?

This is not an emergency. If it had been an emergency, you would have been notified within 24 hours.

People who drink water containing trihalomethanes in excess of the MCL over many years may experience problems with their liver, kidneys, or central nervous system, and may have an increased risk of getting cancer.

What is being done?

We are currently working on solutions to correct the problem. We anticipate resolving the problem in 2015.

For more information, please contact Mr. Brent Wright or Mike Glasgow at 810-787-6537 or the Water Plant at 4500 North Dort Highway, Flint, MI 48505.

Please share this information with all the other people who drink this water, especially those who may not have received this notice directly (for example, people in apartments, nursing homes, schools, and businesses). You can do this by posting this notice in a public place or distributing copies by hand or mail.

This notice is being sent to you by the City of Flint.

CERTIFICATION: F1 S3 WSSN: 02310

I certify that this water supply has fully complied with the public notification requirements in the Michigan Safe Drinking Water Act, 1976 PA 399, as amended, and the administrative rules. Reminder to water supplier: This notice/certification must be sent to the DEQ.

Public reporting burden for this collection of information is estimated to average 5.53 hours per response. This estimate includes time for reviewing the instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the information collected. Burden means the total time, effort, or financial resources expended by person(s) to generate, maintain, retain, or disclose or provide information to or for a Federal Agency. This includes the time needed to review instructions; develop, acquire, install, and utilize technology and systems for the purposes of collecting, validating, and verifying information; adjust the existing ways to comply with any previously applicable instructions; search data sources; complete and review the collection of information; and transmit or otherwise disclose the information. An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for EPA's regulations are listed in 40 CFR Part 9 and 48 CFR Chapter 15.

Send comments on the Agency's need for this information, the accuracy of the provided burden estimates, and any suggested methods for minimizing respondent burden, including through the use of automated collection techniques to the Director, OPPI, Regulatory Information Division, U.S. Environmental Protection Agency (1804A), Ariel Rios Building, 1200 Pennsylvania Ave., NW, Washington, DC 20460, and Office of Information and Regulatory Affairs, Office of Management and Budget, 725 17th Street, N.W., Washington, DC 20503.

Source, Treatment, Storage, and Pumping Inventory

To ensure all potential source, treatment, and storage projects are considered, it may be helpful to complete some or all of this inventory table. However, completion of this table is not required.

- **Source Projects** are all projects related to collecting and pumping raw water. This includes wells, surface water intakes, springs, off-stream raw water storage, and pumps.
- **Treatment Projects** are all projects related to disinfection, filtration, or other treatment processes for ground or surface water sources, or for treatment applied in the distribution system.
- **Storage and Pumping Projects** are related to finished or treated water storage, and booster pump stations.

Transmission and Distribution Inventory

Transmission and distribution projects are the piping needs of a water system. Projects for **valves, backflow prevention devices and assemblies, and meters** that are not part of a transmission or distribution project listed in this table should be recorded in the table under the tab titled "Inventory Table 3".

On the table below, please provide an estimate of the total feet or miles of pipe in your system, if possible. Completion of this table is not required, but it may be helpful to ensure all potential transmission and distribution pipe projects are considered.

Note: The total feet or miles of pipe in your system is required information if any pipe projects are submitted based solely on survey-generated documentation (documentation codes 10 or 11).

☐ feet ☐ miles **Total Pipe in System** *(Check feet or miles)*: _____

	Total Pipe in System *(Check feet or miles)*		<=6 inch	8-12 inch	15-42 inch	>=48 inch
Plastic	_____ ☐ feet ☐ miles	Amount of PVC by pipe size	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles
	_____ % of total pipe	% of this category/size pipe currently in poor condition or beyond useful life	_____ %	_____ %	_____ %	_____ %
Ductile Iron	_____ ☐ feet ☐ miles	Amount of ductile iron by pipe size	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles
	_____ % of total pipe	% of this category/size pipe currently in poor condition or beyond useful life	_____ %	_____ %	_____ %	_____ %
Cast Iron	_____ ☐ feet ☐ miles	Amount of cast iron by pipe size	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles
	_____ % of total pipe	% of this category/size pipe currently in poor condition or beyond useful life	_____ %	_____ %	_____ %	_____ %
Asbestos Cement	_____ ☐ feet ☐ miles	Amount of asbestos cement by pipe size	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles
	_____ % of total pipe	% of this category/size pipe currently in poor condition or beyond useful life	_____ %	_____ %	_____ %	_____ %
Other	_____ ☐ feet ☐ miles	Amount of other by pipe size	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles	_____ ☐ feet ☐ miles
	_____ % of total pipe	% of other currently in poor condition or beyond useful life	_____ %	_____ %	_____ %	_____ %

Meters, Service Lines, Backflow Prevention Devices/Assemblies, Valves, etc.

Projects for meters, service lines, backflow prevention devices and assemblies, valves, and other miscellaneous projects are recorded in this section to accommodate entries of multiple identical items on one line in the project table.

Record only projects that are not a part of another project (e.g., water main replacement projects will already include valves and other appurtenances).
EPA requires documentation of all projects provided. Applicable types of documentation are presented in List 4 of the Lists of Codes.
Use only existing documentation of cost. We do not expect you to develop new cost estimates.

To ensure all potential projects are considered, it may be helpful to complete some or all of this inventory table. However, completion of this table is not required.

Inventory	Needing Replacement	New Infrastructure Needs
Total Number of Existing Water Meters:	Number of Water Meters:	Number of Water Meters:
Total Number of Existing Backflow Prevention Devices/Assemblies:	Number of Backflow Prevention Devices/Assemblies:	Number of Backflow Prevention Devices/Assemblies:
Total Number of Valves:	Number of Valves:	Number of Valves:
Total Number of Lead Service Lines:

City of Flint
Water Reliability Study
Phase 1

June 2010

Prepared by:
ROWE PROFESSIONAL SERVICES COMPANY
and Potter Consulting

Section 1 - Introduction

1.1 Background

The City of Flint currently provides water service to a population of approximately 118,000 through an extensive network of transmission and distribution mains. Many of these mains are aging and are in need of replacement. The city also operates several booster pumping stations and storage facilities to boost pressures and enhance service. The *City of Flint Water System Review* performed by the Michigan Department of Environmental Quality, Drinking Water & Radiological Protection Division in 2008 rated the water distribution system as "deficient", citing key improvements being necessary to the water supply including:

- Distribution system improvements
- Transmission system improvements
- Improvements to pumping stations
- Development of an Asset Management System

The review also states that much of the piping within the City of Flint is more than 70 years old and is in serious need of replacement. The City of Flint Water Service Center, which operates and maintains the water system, spends a significant amount of time repairing mains that are in poor condition. Each winter, a large number of water main breaks occur due to the aging condition of the water mains. These breaks result in interruptions in water service and potential public health risks to city customers.

In response to this deficiency rating the city retained ROWE Professional Services Company to develop a Water System Reliability Study to correct these deficiencies.

Before beginning the Water Reliability Study process, ROWE Professional Services Company met with City of Flint officials and Michigan Department of Natural Resources and Environment (DNRE) staff to determine the goals of the study. These discussions produced a three-phase approach to addressing the issues raised by DNRE.

A. **Phase 1 Model Update and Short Term CIP**

Key tasks include:

- Update the city's water model including demand allocations, pumping and storage facilities, piping changes, and other associated infrastructure
- Update the city's General Water Plan
- Evaluate existing conditions and develop a short-term (6 year) Capital Improvement Plan
- Update the Contingency Plan
- Calibrate the city water model
- Analyze valve and hydrant deficiencies

B. **Phase 2 Distribution System Asset Management and 20-Year Capital Improvement Plan**

Key tasks include:

- Develop modeling scenarios for 20-year water system plan
- Develop 20-year plan for the water system
- Prepare cost opinions for 20-year plan
- Analyze rate structure to support 20-year plan
- Develop an asset management plan
- Inventory water distribution system assets

C. **Phase 3 Water Treatment Plant Asset Management Plan and 20-Year Capital Improvement Plan**

Key Tasks Include:

- Develop modeling scenarios for 20-year water treatment plant
- Develop 20-year plan for the water treatment plant
- Prepare cost opinions for 20-year plan
- Analyze rate structure to support 20-year plan
- Develop an asset management plan
- Inventory water treatment plant assets

1.2 Existing Conditions

A. **Source Facilities**

The City of Flint purchases treated water from the City of Detroit through the DWSD. The treated water is supplied to Flint via a 72-inch transmission main. This transmission main also provides water service to Genesee County and several other communities between Flint and Detroit. The flow to the City of Flint is metered to provide accurate water use records.

The city also maintains a water treatment plant as a backup supply in the event that the City of Detroit water supply is interrupted. Work to upgrade the City of Flint water treatment plant began several years ago and is progressing to completion. A number of test runs were initiated in 2006, 2007, and 2008. Additional test runs are planned for the future. The majority of the improvements at the plant have been implemented as a result. The plant is generally ready for use in a standby capacity, in the event that service from the City of Detroit water supply is interrupted. Long-term plans include provisions for expanding the capacity of the plant and implementing a softening system.

B. **Water Treatment**

The water purchased from DWSD is already treated prior to reaching the City of Flint system; typically, no further treatment is required. The City of Flint also owns and operates a water treatment plant located at 4500 North Dort Highway, which serves as a backup supply in the event of a major

hammer caused by the spring check valves upon start up and shut down of the pumps. This work was budgeted for 2006 and 2007, but never implemented. The city is currently working to implement these upgrades in 2010.

6. Torrey Road Pumping Station

The Torrey Road pumping station is equipped with two centrifugal pumps rated at 2.8 mgd and 4 mgd, respectively. Both pumps were installed in 1954. The station has a total pump capacity of 6.8 mgd and a firm pump capacity of 2.8 mgd. The primary function of this station is as an in-line booster pumping station to provide increase pressures to the southwest portion of the city. This pumping station takes suction from the 24" transmission main along Hammerburg Road and discharges to the 18" transmission main supplying the southwest pressure district. There is no standby power provided to this pumping station.

The City of Flint has made plans to replace the existing pumps and piping in the station. The existing pumps have exceeded their useful life and the piping and valves are in poor condition. The station is scheduled for upgraded pumps and interior piping in 2010. Permit applications were submitted to DNRE in April 2010.

D. Condition of Service Lines

Service lines appear to be in adequate condition with typical repairs made by city staff, depending on the age of the existing water main and water services connected to it. The city does experience problems with a number of existing valves. The long-term needs for the system include replacement of the existing valves over the next 20 years. The total estimated cost to replace the valves is approximately $2,000,000.

E. **Type of Conveyance System**

The conveyance system of the City of Flint consists of water distribution and transmission main ranging in size from 4" to 72" in diameter. Many of these mains exceed 70 years old, and the majority is constructed of cast iron or ductile iron pipe up to 24" in diameter. Transmission mains larger than 24" are primarily constructed of steel piping. A breakdown of the distribution system pipe sizes by percentage is provided in the *City of Flint Water System Review*, prepared by the MDEQ, located in Appendix A.

The majority of the city's system has adequate transmission piping to convey sufficient flows and pressure for fire protection. However, the distribution and transmission system are old and in serious need of replacement. Every year, a large number of water main breaks occur within the city. These breaks, which are repaired by city staff, result in serious water service disruptions and potential water quality problems to customers of the City of Flint. The six year Capital Improvement Program in Table 1 is intended to remedy the most pressing of these infrastructure problems and Phase 2 of this study will take a long term look at system wide problems and solutions.

project 0009

- Phase I of Rel. & Lt. Study

Table 1: 6-Year Capital Improvement Table

Project Number	Capital Improvement Program	Design Status	Construction Status	2010 Construction Costs	Contingencies, Engineering, Management Legal (CEM&L @ 47%)	Total CIP Project Cost

Subject: RE: Briefing on Karegnondi Project/City of Flint

Just so everyone is on the same page:

Karegnondi Water Authority (KWA) has received a permit to construct an intake structure in Lake Huron from DEQ. If not already started, construction is planned for this fall.

I recall some discussion with Genesee County about using the raw water line to also provide water for agricultural purposes and possibly a utility in the area. Staff (Mike Prysby) is meeting with the county Wednesday to discuss big picture technical items on the project. We will be sure to remind the county at this meeting that the water withdrawal permit is restricted to drinking water use.

When we met with KWA and the city of Flint last spring, Flint had not yet decided whether to join the authority or not. We have not received word that a decision has been made. At one time, it appeared that DWSD would allow the city of Flint to blend DWSD water with Flint River and/or KWA drinking water; however we have heard third-hand that this may not be acceptable to DWSD. We have not seen anything in writing.

Andy Dillon is getting pulled into this issue. Andy asked the Governor at the Group Executive meeting if the administration has a position on this project. The Governor said he needs to know more. I think we have all been

approached on this project. Keith/Jamie, have you taken a position on this? Bill, am I correct in saying this will have effect on DWSD?

Subject: Karegnodi Water Authority (Genesee County Drain Commission) Intake Meeting

On April 10, 2012, a meeting was held at the Saginaw Bay District office to discuss the Karegnodi Water Authority's proposed intake into Lake Huron. Present at the meeting representing the Genesee County Drain Commission were John O'Brien, Matthew Raysin, and David Jansen, from Rowe Engineering was James Reddding, the USACOE was Mark Lesinski, and the DEQ were Cathy Sleight and Jon Bloemker.

The Authority is now an incorporated P.A. 233 agency based in Sanilac County. The intake has received a withdraw permit for up to 85 MGD. The authority is proposing to install about one mile of 78-inch line into Lake Huron to about a water depth of 35 feet. The single line will utilize two intakes, each housed in 65 foot diameter octagon, timber cribs. The 78 inch line will be paralleled by a single, 16 inch line acting as a sleeve for three, 4 inch plastic chlorine solution lines. The proposal calls for boring the first 700 to 3,800 feet of the 78 inch line from the west side of M-25 to the east into the lake. The final distance will be opened cut. The length of the bore will be dependent on the soils and the amount of boulders encountered. The bored section of the 78 inch line will be reinforced concrete pipe, and the open cut portion of the line will be either reinforced concrete or steel. The opened cut portion of the line will be bedded with native material and stone. Large stone riprap armor the area above the trench.

The county was warned that typically two intake lines are normally required due to reliability, frazil ice, security and maintenance issues. The county was told that the department would entertain a signed agreement with Detroit and/or Flint to provide back up emergency service in the event of any problems with the single intake line.

The county was informed about the WRD and/or USACOE permitting requirements for construction near the shoreline, a declared beach erosion area and along the lake bottom. The county was told that it would need to contact the DNR regarding the construction season due to spawning and migrations and to obtain a Part 21 easement for the lake bottom construction. There were discussions about spoil disposal, estimated at 35,000 yd^3. A few of the issues surrounding the testing and depositing the spoils in a DMDF and/or upland area were discussed. It was suggested, due the amount of virgin soils, that the county may want to talk to a few of the area's landfills about free or a moderately cost daily cover material. The county was told that side casting the spoils from the dredging back into Lake Huron would be prohibited.

The county and consultant were told that at present the Saginaw Bay District is planning on reviewing the intake, the low lift station and the raw water line to the treatment plant. Also, they were told that the Lansing District would review the treatment plant.

The county hopes to submit its applications in June and start construction in October.

Director - Treasury - Flint

Meeting at O.R 9AM

Tue 3/26/13

HARd to eval cost overruns

2 things Objective for this meeting
- Agree w. Assessment
- Ed study & justify the $$
- Ed the ?s we want to ask
- Put Pros/Cons on table beyond cost

may have to go thru.

Ag. use of KWA - PWSL Hearing Process Possible & Potential for New withdrawal Permit

KWA doubt - $$ cost overruns)

12 Points WRN sees

1. KWA $ ↓ as we are going along
2. Blending not Needed
   - $ costs not needed
   - $ PWSA Health
   - other inputs - NPDES
3. Not exp of Flint - Econ potential
4. 6% impact on DWSD vs 2% if only Flint
5. Why are the 2 orgs ADD-ons ↑ costs - TRP w. KWA options
6. Cost overruns & how it's factored in
7. GLOCom is going regardless

8.

What is QWSD doing to see what step Float Farm Bakery away? Alt note size if not stored now 30 yr contract

CH OTF3 - Ag Power Mkt
- see on table 5
- Could water use/level lag - Kaynes?

Overall
- Ag - Bosmere 2 yrs - working Approx Fa
- Ag - ERR - not Peachtree - Need to current Point if Ag use ire develops could be in the future

Larger scale Question for Thought KWA vs. DWSD

What are the future Rates for Both systems?

* Both are tech. OK to a certain extent (Both overlap some issues) *

Is there enough value gained on keeping that DWSD system together?

What authority do we have? — Powers issued by us

If Flint signs long-term contract w. DWSD who establ. Base-rate? Specifics? Termination Clause?

* We support Regional W-S — there are 2 capacity can't say Adv. of one over the other *

* Why if Lapeer left as off why are G/M rates from WTP not S.G. Lod?

KWA - seems cut-off —
Bland - reasons we can make cut-off - Canton - has left Regional
S.S Finland Sought to keep Regional system?

City of Flint
2011 Needs Survey
Comments/Questions – October 24, 2011

Source, Treatment, Storage, and Pumping Projects

The city retained a Lockwood, Andrews & Newnam (LAN) (Spring 2011) to investigate and determine WTP improvements that will be needed to produce a finished water quality that meets the Michigan safe drinking water standards based upon treatment of the Flint River water on a continuous basis. A draft copy of the investigation report was included with the 2011 Needs Survey. Some of the projects listed in the survey are based on the investigation. Also, the city of Flint completed Phase I of their water system Reliability Study in 2010 that identifies needed water distribution/transmission improvements. Finally, the 2009 DWRF Project Plan – identified similar needs.

Project #

1000 - This project reflects the need to continue making SCADA improvements for Phase II WTP upgrade. The cost estimate is being changed to $720,000 based on LAN's estimate (Page 5 of 12). Also, the design capacity is changed to 28 MGD based on LAN's report.

1001 thru 1006.

Projects 1001-1005 reflect the need to replace the low and high service pumps at P.S. 4 during the 20-year planning period. Project 1006 reflects the need for a pump station to allow the WTP to send treated water to the Dort Reservoir. Projects 1001-1006 will be combined with Project 1012 – Water Treatment Plant Expansion and re-designated as Project 1001 since the low and high service pumps at P.S. 4 are part of the WTP expansion. Also, since the Dort Reservoir will be needed for CT, the new pump station (listed as Project 1006) is considered part of the WTP expansion.

1007 – 1009

These projects reflect the need to replace the booster pumps at P.S. #3 and are carried over from the 2007 survey. MDEQ staff changed Documentation codes #1 and #11 to #20 since these projects rely on the 2007 assessment documentation. MDEQ staff updated the respective project number for each project.

1010 -1011

These projects reflect the need for stand-by power at P.S. #3 and #5 and are carried over from the 2007 survey. MDEQ staff changed Documentation codes #1 and #11 to #20 since these projects rely on the 2007 assessment documentation. MDEQ staff updated the respective project number for each project.

1012 - This project reflects the need for a WTP rehabilitation and is carried over from the 2007 survey. MDEQ staff revised the design capacity to 28 MGD based on LAN's report. Given the scope of the project, staff also renamed the project as a Water Treatment Plant Expansion and combined it with Projects 1001-1006. Docc. Code #11 was changed to Code #2 since an engineer's report is available.

1013 – This project reflects the need replace the electrical switchgear at P.S. No. 3 and is carried over from the 2007 survey. The engineer's cost estimate is provided; thus, this project was not combined with Projects 1007-1009 (replace pumps at P.S. No. 3). MDEQ staff changed Documentation Code #3 to #2 based on the preliminary cost estimate. The project need is also documented in the April 2009 DWRF Project Plan; however, the cost estimate was revised in July 2011 – thus both dates will serve for the cost estimate and supporting documentation.

1014 – This project reflects the need to rehabilitate the Torrey Road PS. MDEQ staff changed Documentation Code #3 to #2 based on the cost estimate. The project need is documented in the April 2009 DWRF Project Plan as a new pump station; however, need has changed to a rehabilitation of the existing station. A copy of the engineer's letter (dated 8/30/2011) explains the reason for the change in need. Since the cost estimate was revised in July 2011 – both dates will serve for the cost estimate and supporting documentation.

1015 – 1016

These projects reflect the need to rehabilitate the Cedar Street and West-side water storage reservoirs within the 20-year planning period. MDEQ staff changed Documentation Code #1 to #20 since these projects rely on the 2007 assessment documentation.

1017 – This project reflects the need to rehabilitate Pump Station #5 within the 20-year planning period. This project is also carried over from the 2007 survey. MDEQ staff changed Documentation Code #1 to # 20 since this project relies on the 2007 assessment documentation.

1018 – This project (rehabilitation of the pumps at P.S. #3) was deleted by MDEQ

staff since Projects 1007 – 1009 provide new pumps at P.S. #3. These pumps cannot be replaced and rehabilitated within the same 20-year planning period.

Transmission & Distribution Projects

2000 - This project reflects the need to replace existing 3 and 4-inch WM with new 8-inch WM and is a carry over from the 2007 survey. MDEQ staff will switch the New code (N) to Replacement code (R). Staff also changed Documentation Code #1 to # 20 since this project relies on the 2007 assessment documentation. Finally, staff revised the cost estimate to $12,000,000 which is consistent with previous documentation.

2001 – This project reflects the need to replace critical 6-inch mains with 8-inch and is carried over from the 2007 survey. MDEQ staff changed the New code (N) to Replacement code (R). Staff also changed Documentation Code #1 to # 20 since this project relies on the 2007 assessment documentation. Finally, the cost estimate was changed to $1,000,000 which is consistent with previous documentation.

2002 – This project reflects the need to loop existing 6-inch WM with 8-inch WM and is carried over from the 2007 survey. This project was deleted by Cadmus in 2007 due to insufficient documentation of the project need at specific locations. MDEQ staff will maintain this project; however, the length of WM will be changed from 3,500 LF to 3,025 LF. The change is based upon Flint's 2009 DWRF Project Plan. The cost estimate was also increased to $470,000 based on the provided estimate. A copy of the looping projects and their cost is provided. Staff also added Documentation #2 based upon the engineer's recommendations.

2003 – This project reflects the need to loop existing 12-inch WM and is carried over from the 2007 survey. This project was deleted by Cadmus in 2007 due to insufficient documentation of the project need at specific locations. MDEQ staff will maintain this project based upon Flint's 2009 DWRF Project Plan. The cost estimate was also increased to $185,000 based on the provided estimate. A copy of the looping projects and their cost is provided. Staff also added Documentation Code #2 based upon the engineer's recommendations.

2004 – 2007

These projects reflect the need to replace existing 6-inch through 16-inch WM and are carried over from the 2007 survey. This project was reduced in scope by Cadmus in the 2007 survey to less than 10% of the total amount of WM replacement in each size category since sufficient independent documentation was not provided.

The 2010 reliability study, the 2009 DWRF Project Plan, and the 6-year CIP identifies WM replacement projects; however, they do not comprise of 10% of the distribution system by size category. MDEQ staff will maintain these projects based on the amount allowed by Cadmus in the 2007 survey. Staff changed Documentation Code #1 to # 20 since these projects rely on the 2007 assessment documentation.

2008 - This project reflects the need to replace 18-inch mains. MDEQ staff changed the length of pipe to 19,800 LF based upon the 2009 DWRF Project Plan. A cost estimate of $7,700,000 was added based on the DWRF preliminary cost estimate (Oct 2011 update). Documentation Code #2 was also added based upon the engineering report and cost estimate.

2009 – This project reflects the need to replace 24-inch mains. MDEQ staff changed the length of pipe to 53,500 LF based upon the 2009 DWRF Project Plan. A cost estimate of $17,500,000 was added based on the DWRF preliminary cost estimate (Oct 2011 update). Documentation Code #2 was also added based upon the engineering report and cost estimate.

2010 – This project reflects the need to replace 30-inch mains. MDEQ staff changed the length of pipe to 5,800 LF based upon the 2009 DWRF Project Plan. A cost estimate of $2,600,000 was added based on the DWRF preliminary cost estimate (Oct 2011 update). Documentation Code #2 was also added based upon the engineering report and cost estimate.

2011 This project reflects the need to replace existing 36-inch mains and is carried over from the 2007 survey. This project was reduced in scope by Cadmus in the 2007 survey to less than 10% of the total amount of WM replacement for that size category since sufficient independent documentation was not provided. Staff changed Documentation Code #1 to # 20 since this project relies on the 2007 assessment documentation.

2012 This project reflects the need to loop existing 8-inch WM and was carried over from the 2007 survey. This project was deleted by Cadmus in 2007 due to insufficient documentation of the project need at specific locations. MDEQ staff will maintain this project based upon Flint's 2009

DWRF Project Plan. The cost estimate was also changed to $6 5,000 based on the provided estimate. A copy of the looping projects and their cost is provided. Staff also added Documentation Code #2 based upon the engineer's recommendations.

2013 – 2014

These projects reflect the need to replace existing 42 and 72-inch WMs and are carried over from the 2007 survey. The scope of these projects were also reduced by Cadmus in the 2007 survey to less than 10% of the total amount of WM replacement in their respective categories since sufficient independent documentation was not provided.

MDEQ staff will maintain these projects; however, the length of WM in each size category will be reduced to the amount allowed by Cadmus in the 2007 survey. Staff will also change Documentation Code #1 to # 20 since this project relies on the 2007 assessment documentation.

Other Projects – Meters, Hydrants, Valves, Etc.

3000 – 3014

These projects reflect the need to continue replacing residential and commercial meters ranging in size from 5/8-in to 24-in and are carried over from the 2007 survey. The number needed in each size category for the 2011 survey is less than the number needed in the 2007 survey since some the meters have been replaced since 2007. MDEQ staff redesignated these projects as a Replacement (R) instead of New (N). Staff also changed Documentation Code #1 to # 20 since these projects rely on the 2007 assessment documentation.

3015 - This project references the need to replace "other commercial meters". MDEQ staff deleted this project since a size was not provided and cannot be modeled by Cadmus.

3016 This project reflects the need to replace lead service lines. This project is not a direct carry over from the 2007 survey since the size and number of services was increased to 1-inch and 18,000 respectively. MDEQ staff re-designated these projects as a Replacement (R) instead of New (N). .

3017 – 3018

These projects reflect the need to replace service lines (1-inch and > 1-inch). MDEQ staff re-designated these projects as a Replacement (R) instead of New (N).

Re: City of Flint DWRF
Project Clarification

Dear Mr. Worthington:

Based on the discussions at our meeting regarding the City of Flint's DWRF projects, we are submitting the following project summary for the three projects that have been requested to be included in the FY 2012 PPL.

24-inch Water Main

The 24-inch water main project has not significantly changed since the submittal to the MDEQ and issuance of the construction permit. The project still includes the replacement of the transmission water main from the Water Treatment Plant west to Dupont Street then south to University Avenue.

Although titled "24-inch water main" the project consists of the replacement of water main ranging in sizes from 6-inch to 30-inch with the majority of it being 24-inch diameter.

The replacement of this main transmission main will provide the city with the reliability to provide water to the western and southwestern portions of the city.

Torrey Road Booster Station – scaled down from 4/09 project plan

The Torrey Road Booster Station project has changed scope since the original thought that a total replacement was required. When the project was to be a total replacement, General Motors was considering expansion to their Bristol Road/Van Slyke complex. General Motors was also experiencing low flow conditions within the existing facilities.

Since that time, General Motors has changed their plans for expanding their facilities and also have resolved the low pressure issues by making internal changes. As a result, the total replacement of the Torrey Road Booster Station is not necessary; however, modifications to the existing station are required to provide reliability to the water customers.

The revised project includes replacement of both booster pumps; piping; valves and electrical gear located within the booster station. The structure itself is in adequate condition therefore only the components need to be replaced.

The station houses two booster pumps with only one currently in operation. The city is not able to run the second (larger) pump as it is oversized for the current demand in the system and has caused water main breaks to occur when it has been run the past. By replacing both the pumps and sizing them to meet the current system demand, the system will again have reliability.

In addition, the project includes the addition of a standby generator hookup which will provide the city the ability to move in a portable generator to provide power in times when the main power feed from Consumers Energy is not available. The city currently has an outside contract to provide power to their Water Pollution Control Facilities that will be enhanced to include the water booster stations. A copy of this contract is attached for your reference.

An application was previously submitted to the MDEQ for review and issuance of a construction permit for the revised project but we understand that due to several factors, the application was never acted upon.

Cedar Street

The Cedar Street project has not changed from the original project and the permit issued by the MDEQ. The project still consists of the replacement of the electrical switch gear and the installation of provisions for generator hookup. The age of the existing electrical equipment does not allow the city ease for maintenance. As parts fail, the city has to rebuild rather than ordering new replacement parts.

The provisions for standby generator hookup will provide the reliability that is required for the water system. As mentioned above, the city will modify the outside contract to include Cedar Street.

As discussed, the city is willing to resubmit new construction permit applications for all three of these projects if the MDEQ feels this will provide a clean file. The application can be submitted as one permit for all three projects or we can prepare three individual applications.

We trust that this letter summarizes our discussions at the meeting. If you have any questions, please contact me at (810) 341-7500.

Sincerely,
ROWE Professional Services Company

Jeffrey B. Markstrom, P.E.

Importance: High

Director Wyant, and Deputy Director Sygo,

Addendums to ODWMA comments provided yesterday regarding the City of Flint water system and comments on the reports from Tucker, Young, Jackson, Tull, Inc. (TYJT) can be found below in red. Additional comments are as follows:

With regards to regulatory authority for DEQ to allow or prevent the breakup of water utilities, and State vs. local decisions about cost effectiveness, it is important to note that when the DEQ permitted the water withdrawal for KWA (permit 2009-001) part of the decision making process (copy attached) included reasonable use and the balance of Economic Development, Social Development, and Environmental Protection. As part of the public participation process general comments were received (pages 6 & 7) regarding impacts on DWSD and rates to remaining customers. The Department's response to those comments stated:

"The DEQ is specifically precluded from using part 327 to "...diminish or create any existing authority of municipalities to require persons to connect to municipal water supply systems as authorized by law" (MCL 324.32726)."

And

"It is appropriately an issue for water service contract negotiations between the regional water system and its customers. To do otherwise invites unwanted intervention of the state into local decision making."

ODWMA cannot on its own assess an actual dollar value to any regional benefit for the City of Flint to remain a full customer of DWSD, but the following should be included in any additional analysis:

- The cost estimates provided in the TYJT report show a cost difference between full KWA and full DWSD participation of $172 million over 30 years.
- The formation of KWA would itself be considered one of the largest regional drinking water authorities in the State in terms of capacity, and as such any regional benefits provided by DWSD may only be marginal in comparison.

Finally, we have additional questions for TYJT regarding the various DWSD supply options and the considerations they made in the operations of the Flint WTP. These considerations will have an impact on the cost estimates for DWSD options.

We look forward to further discussion of these comments during our meetings tomorrow, and please let us know if you have any additional questions for us between now and then.

Subject: Flint Draft Response

Director Wyant,

In preparation for our call today with Treasurer Dillon's office, ODWMA has developed the following for consideration. We can provide any additional info you require during the meeting.

ODWMA has reviewed the materials developed by the consultant Tucker, Young, Jackson, Tull, Inc. (TYJT) for Treasury regarding the City of Flint and potential alternatives for public water supply. Based on our reviews, we have developed the following comments to this point in our analysis:

1. The TYJT report does not contain the full scope of the Karegnondi Water Authority (KWA) raw water supply system. TYJT concerns over raw water supply redundancy and reliability are addressed to the satisfaction of ODWMA under the full KWA proposal. Please note some portions of the overall project are being financed independently by the Genesee County Drain Commission.

2. There are significant differences in contract language between KWA and Detroit Water and Sewerage Department (DWSD) with respect to the contracted maximum day demand capacity.
    a. Under a KWA contract, a "maximum day" capacity of 18 million gallons per day (MGD) would fully satisfy current demands of the City of Flint, without the need to supplement raw water capacity using the Flint River. (18 MGD, average over a 30 day period).
    b. Under a DWSD model contract, a "maximum day" capacity, even at 18 MGD, would not satisfy the current demands for the City of Flint. (18 MGD, over any 24 hour period).

3. Restrictions in contracted capacity that would prevent the City of Flint from meeting peak demand requirements present potential limits to economic development within the City of Flint, including possible connection bans and water system extension bans. This information was previously conveyed to the City of Flint by ODWMA staff.

4. All contract options with DWSD that are considered semi-competitive with the KWA contract do not fully supply the City of Flint, and would require the City of Flint to meet a significant, if not majority, of its water demands by treating water from the Flint River. Continuous use of the Flint River at such demand rates would:
    a. Pose an increased microbial risk to public health (Flint River vs. Lake Huron source water)
    b. Pose an increased risk of disinfection by-product (carcinogen) exposure to public health (Flint River vs. Lake Huron source water)
    c. Trigger additional regulatory requirements under the Michigan Safe Drinking Water Act (LT2ESWTR)
    d. Require significant enhancements to treatment at the Flint WTP, beyond those identified in the TYJT report (see item 5 below).
    e. Water Resource Division is evaluating potential impacts to NPDES wastewater discharge permits in downstream segments of the Flint River, as a result of decreased river baseflow caused by Flint WTP use.

5. The TYJT report does not adequately address increased requirements and costs associated with using the Flint River as a significant source for the Flint WTP, which are not necessary under a Lake Huron source water scenario. This includes:
    a. The need to provide softening treatment
    b. Limitations on disposal options for lime softening sludge
    c. Increased ozone capacity, UV disinfection
    d. Additional backup power, more power required for Flint River operation

6. The Flint WTP must operate at some minimum level and within a range of flow rates to maintain treatment effectiveness. Currently that minimum level is 9 MGD. This level may be reduced with additional capital costs to modify the WTP, not addressed in the TYJT report.

7. Allowing Flint WTP to blend water with DWSD sets a new precedent that could pose future consequences with other DWSD customers.

8. Costs impacts to remaining DWSD customers would be similar under the proposed scenarios, only retaining 8 MGD of 30+ MGD total Flint/Genesee Co. demands, based on the following:
    a. Genesee County distribution system demands are pulling out of DWSD regardless of the decisions by Flint WTP
    b. Flint's need to utilize the Flint River as a source

9. ODWMA anticipates cost savings under the KWA proposal will be leveraged to provide additional improvements to the City of Flint water distribution system, improving efficiency and providing additional cost benefits. The KWA water withdrawal permit (2009-001) includes the required implementation of conservation measures that would also drive these distribution system improvements.

10. Major cost discrepancies in TYJT analysis
    a. Engineering, Legal, Administration, Contingency – TYJT appears to have effectively double charged for these costs in their KWA estimates without adequate justification
    b. Pumping facilities – TYJT cost estimate methodology does not appear to address localized market costs and does not distinguish fixed and variable costs in its comparison analysis.

11. Remaining DWSD customers in Lapeer County could potentially see water quality impacts as a result of Flint joining KWA, if they remain with DWSD. However, indications to ODWMA are that these communities are currently in final negotiations with KWA for service, which would make this a non-issue.
    a. City Lapeer
    b. City of Imlay City

Additional response to the TYJT report has also been provided by Rowe Engineering to Flint EFM, Mr. Ed Kurtz. (Copy Attached)

ODWMA has continued to meet on a regular basis with KWA, Genesee County, and the City of Flint regarding these water supply proposals.

ODWMA will continue to provide any additional detailed analysis requested by Treasury or the DEQ Executive Office.

Please note some portions of the overall project are being financed independently by the Genesee County Drain Commission.

2. There are significant differences in contract language between KWA and Detroit Water and Sewerage Department (DWSD) with respect to the contracted maximum day demand capacity.
    a. Under a KWA contract, a "maximum day" capacity of 18 million gallons per day (MGD) would fully satisfy current demands of the City of Flint, without the need to supplement raw water capacity using the Flint River. (18 MGD, average over a 30 day period).
    b. Under a DWSD model contract, a "maximum day" capacity, even at 18 MGD, would not satisfy the current demands for the City of Flint. (18 MGD, over any 24 hour period).

3. Restrictions in contracted capacity that would prevent the City of Flint from meeting peak demand requirements present potential limits to economic development within the City of Flint, including possible connection bans and water system extension bans. This information was previously conveyed to the City of Flint by ODWMA staff.

4. All contract options with DWSD that are considered semi-competitive with the KWA contract do not fully supply the City of Flint, and would require the City of Flint to meet a significant, if not majority, of its water demands by treating water from the Flint River. Continuous use of the Flint River at such demand rates would:
    a. Pose an increased microbial risk to public health (Flint River vs. Lake Huron source water)
    b. Pose an increased risk of disinfection by-product (carcinogen) exposure to public health (Flint River vs. Lake Huron source water)
    c. Trigger additional regulatory requirements under the Michigan Safe Drinking Water Act (LT2ESWTR)
    d. Require significant enhancements to treatment at the Flint WTP, beyond those identified in the TYJT report (see item 5 below).
    e. Water Resource Division is evaluating potential impacts to NPDES wastewater discharge permits in downstream segments of the Flint River, as a result of decreased river baseflow caused by Flint WTP use.

5. The TYJT report does not adequately address increased requirements and costs associated with using the Flint River as a significant source for the Flint WTP, which are not necessary under a Lake Huron source water scenario. This includes:
    a. The need to provide softening treatment
    b. Limitations on disposal options for lime softening sludge
    c. Increased ozone capacity, UV disinfection
    d. Additional backup power, more power required for Flint River operation

6. The Flint WTP must operate at some minimum level and within a range of flow rates to maintain treatment effectiveness. Currently that minimum level is 9 MGD. This level may be reduced with additional capital costs to modify the WTP, not addressed in the TYJT report.

7. Allowing Flint WTP to blend water with DWSD sets a new precedent that could pose future consequences with other DWSD customers.

8. Costs impacts to remaining DWSD customers would be similar under the proposed scenarios, only retaining 8 MGD of 30+ MGD total Flint/Genesee Co. demands, based on the following:
    a. Genesee County distribution system demands are pulling out of DWSD regardless of the decisions by Flint WTP
    b. Flint's need to utilize the Flint River as a source

9. ODWMA anticipates cost savings under the KWA proposal will be leveraged to provide additional improvements to the City of Flint water distribution system, improving efficiency and providing additional cost benefits. The KWA water withdrawal permit (2009-001) includes the required implementation of conservation measures that would also drive these distribution system improvements.

10. Major cost discrepancies in TYJT analysis
    a. Engineering, Legal, Administration, Contingency – TYJT appears to have effectively double charged for these costs in their KWA estimates without adequate justification
    b. Pumping facilities – TYJT cost estimate methodology does not appear to address localized market costs and does not distinguish fixed and variable costs in its comparison analysis.

11. Remaining DWSD customers in Lapeer County could potentially see water quality impacts as a result of Flint joining KWA, if they remain with DWSD. However, indications to ODWMA are that these communities are currently in final negotiations with KWA for service, which would make this a non-issue.
    a. City Lapeer
    b. City of Imlay City

Additional response to the TYJT report has also been provided by Rowe Engineering to Flint EFM, Mr. Ed Kurtz. (Copy Attached)

ODWMA has continued to meet on a regular basis with KWA, Genesee County, and the City of Flint regarding these water supply proposals.

ODWMA will continue to provide any additional detailed analysis requested by Treasury or the DEQ Executive Office.

EMERGENCY MANAGER
CITY OF FLINT
GENESEE COUNTY MICHIGAN

ORDER No. 31

WATER AND SEWER RATE INCREASES

BY THE POWER AND AUTHORITY VESTED IN THE EMERGENCY MANAGER ("EMERGENCY MANAGER) FOR THE CITY OF FLINT, MICHIGAN ("CITY") PURSUANT TO MICHIGAN'S PUBLIC ACT 4 OF 2011, THE LOCAL GOVERNMENT AND SCHOOL DISTRICT FISCAL ACCOUNTABILITY ACT, ("PA 4"); MICHAEL BROWN, THE EMERGENCY MANAGER, ISSUES THE FOLLOWING ORDER:

On March 16, 2011, the Local Government and School District Fiscal Accountability Act, Public Act 4 of 2011, ("Public Act 4") was enacted to safeguard and assure the fiscal accountability of units of local government; to preserve the capacity of units of local government to provide or cause to be provided necessary services essential to the public health, safety and welfare of citizens; and

Governor Rick Snyder appointed Michael Brown as the Emergency Manager for the City of Flint on November 28, 2011, and his contract was approved by the State Treasurer on November 29, 2011; and

Pursuant to Public Act 4, the Emergency Manager has broad powers in receivership to rectify the financial emergency and to assure the fiscal accountability of the City of Flint and its capacity to provide or cause to be provided necessary services essential to the public health, safety and welfare; and

Pursuant to Public Act 4, the Emergency Manager acts in place of local officials, specifically the Mayor and City Council, unless the Emergency Manager delegates specific authority; and

Pursuant to Public Act 4, the Emergency Manager may take any action or exercise any power or authority of any officer, employee, department, board, commission, other similar entity of local government, whether elected or appointed, relating to the operation of local government.

Under state law the City has an obligation to set water and sewer rates that are sufficient to cover the costs of operating the water and sewer systems. See MCL 141.121.

The City of Flint determined that it was necessary to raise water and sewer rates, effective September 16, 2011, to adequately cover the system costs and comply with state law. And because the September 16, 2011 rate increases are insufficient to cover the costs of operating the water and sewer systems and pay outstanding bonded indebtedness on the water system, it is necessary to raise rates again, effective July 1, 2012.

Both the September 16, 2011 rates increases and the July 1, 2012 rate increases are necessary to comply with state law. Without the rate increases, the City would run a deficit in both the water and sewer funds.

It is hereby ordered:

The September 16, 2011 rate increases are expressly ratified and confirmed as of September 16, 2011.

Water and sewer rates are revised, effective July 1, 2012, as shown on the attached rate schedules.

Any local ordinance or regulation that is inconsistent with or limits the City's ability to comply with its obligation under state law to charge water and sewer rates that cover the costs of operating the systems and pay bonded debt are invalid, effective September 16, 2011.

This Order shall have immediate effect and is for immediate publication.

This Order may be amended, modified, repealed or terminated by any subsequent order issued by the Emergency Manager.

Dated: May 30, 2012

Cc: Poy, Thomas; Bair, Rita; Damato, Nicholas; Murphy, Thomas; Shoven, Heather; Kuefler, Janet; Deltoral, Miguel
Subject: Call with EPA-Cincinnati, Office of Research and Development

Mike—below are the notes from the call we had last week regarding Legionella, as we discussed. You also mentioned that I should remind you to:

1. check with Mike Glasgow at Flint to ask about their flushing strategy; what types of flushing they are conducting; and
2. that you will send me the March MOR when you receive it in April. (Kris Donaldson from Warren office sent me the March 2014 MOR for Flint w/Detroit water.)

Both of these items above were discussed by Darren Lytle; that these documents will provide him basic data about the Flint water system.

Thank you!

Jennifer

Summary:
Last Thursday, March 26, we talked with Darren Lytle, Acting Chief of the Treatment Technology Evaluation Branch at EPA-Cincinnati, Office of Research and Development. Also in attendance was Simoni Triantafyllidou, a post-doctoral fellow working with Darren. Tom Poy, Nick Damato, Janet Kuefler, Miguel, and Jennifer were also in attendance.

Tom Poy summarized for Darren and Simoni what has occurred with the Flint drinking water since April 2014 when the change over from Detroit to Flint River water occurred, including the violations Flint has incurred since then. Miguel said that we don't know if Flint has a lead problem at this time. Due to findings by Genessee County Health Dept. that there has been an increase in the incidence of Legionella since April 2014, Genessee CHD has FOIA'd the City of Flint for operational data.

Darren talked about several treatments they have done for Legionella in 2 hospitals. The first treatment used copper/silver ions for disinfection. They did sampling at 10 locations, took water quality parameters and took microbiological samples. But they shut down the treatment due to staining of toilets on the cold water side. They did turn the treatment back on, only on the hot water side. The second treatment is a monochloramine system in the hot water feed, but the secondary effects are nitrification.

Darren said they have been doing studies for Homeland Security, collecting sediments at the bottom of storage tanks. He is finding high concentrations of Legionella in the bottom of the tanks.

Darren said anytime there is a treatment change, issues arise with the drinking water quality. Thus, what does this do to the transport of organisms like Legionella? Does is cause organisms to desorb and go into solution? The changes in water chemistry change these organisms electrostatically, and the biofilms with the distribution system pipes are disrupted and de-stabilize. Thus, different contaminants can be released. So maybe this isn't happening in people's homes; but it is happening in the distribution system pipes.

Darren thought that the incidence of Legionella must be fairly extensive for the CHD to notice and study.

We talked about the pathogen, Legionella. Simoni said that Legionella is everywhere; it is a group of opportunistic pathogens; meaning that it looks for high risk/immunocompromised hosts to infect. It may infect others but not show signs of disease because their immune system is working properly. Simoni was interested in knowing where are these cases of Legionella occurring? The background information/data is important in a study of the incidence of Legionella. Jen said she would gather data from past use of Detroit water (March 2014 monthly operation report-MOR), and recent MORs from use of Flint River water, and TTHM levels since April 2014. Tom Poy said that the Dept of Community Health is communicating with the Genessee CHD regarding their findings on Legionella.

Miguel said that extensive flushing is going on in Flint to address stagnant water that fosters bacti problems and TTHM development. But, stirring up the distribution system lines with flushing is stirring up the sediment in the pipes, and then causes a large chlorine demand, thus decreasing the chlorine residual which could promote the growth of bacteria, such as Legionella. Chlorine residual will come back gradually, though. Jen said she would check in with the State to find out the details of Flint's flushing program; is it unidirectional for example?

Darren asked, How can we help? He offered to conduct sampling and analyses for Legionella when it is needed. Tom Poy said the State is currently figuring out a communication-with-the-public plan. Mike Wright is the HQ-ORD DDBP expert and he is helping with the TTHM health effects issue. Tom Poy said that we are laying a foundation now with resources for when the State goes public with the issue of Legionella. Darren said that the labs are set-up now ready for Legionella sampling and analyses. Mark Rodgers is the Chief of the Microbial Contamination Branch at EPA-Cincinnati, ORD.

Darren is doing a RARE project in Region 3 on Legionella. EPA could work on the DNA to determine if the Legionella infecting people is from the distribution system. Type 1 Legionella causes disease, but other forms of Legionella do not cause disease. But Darren said, we must identify the source of the Legionella first.

Miguel said that we must look at the overall picture, i.e. is the system causing this increased incidence of Legionella disease? Darren said that first, we must find the source—is Legionella there? If Legionella is present, in the tanks/pipes, then disturbance of changing the water quality and flushing, could cause it to proliferate.

END

Thanks Mike and you are correct Wed meeting at 1:30PM your office. John and Dave plus Elgar.
The agenda is to meet Steve, generally go over the project i.e. KWA report dated 2009, discuss who is in and who maybe out, current status interms of the intake bidding, preparation of preliminary design by Wade Trim, projected timeline for letting more engineering design contracts, projected start up of the project and financing (bonding) update. Important to discuss the current status of Flint City and DWSD as well.
Probaly take several hours. It would be a good idea to set a time for Steve to come to the GCDC office and sit in on a preliminary design meeting with WT etal to get a feel for the final preliminary design criteria and to seek MDEQ input. Suggest that both you and Jon be in attendance. Early Feb. probaly best to really kick off the design. We can set the meeting Wed. To insure all on board.
Any questions let me know and we look forward to the meeting. We will ask for you at 1:30.
John O'

Lansing, MI 48909

Administrator McCarthy and Director Wyant:

The attached June 24, 2015, memorandum between two Environmental Protection Agency (EPA) employees, Miguel A. Del Toral and Thomas Poy, published recently by the American Civil Liberties Union of Michigan, suggests that there are high lead levels in the city of Flint, Mich., water traces

- Are the findings in the memorandum regarding the lead levels in the city of Flint water accurate?
- If there were in fact high levels of lead in the water in the city of Flint, when did the EPA and/or MDEQ plan to alert the public?
- What, if any, of the recommendations has the EPA followed from the memorandum?
- Given the demonstrated level of lead in the water in Flint, MI, is the water safe?

Regardless, I am very troubled by recent tests suggesting high levels of lead in the city of Flint's water system. As you know, on the EPA's website it says that lead above the "action level" in drinking water can cause a variety of adverse health effects, including delays in physical and mental development in babies and children.

According to the Safe Drinking Water Act, the EPA has the responsibility of enforcing water quality standards. EPA, however, has given the primary responsibility of enforcing water quality standards to the state of Michigan via MDEQ. As such, it is the responsibility of these agencies to ensure that the people of the city of Flint have safe drinking water.

Thank you and I look forward to hearing from you soon.

Sincerely,

Dan Kildee
MEMBER OF CONGRESS

MEMORANDUM

SUBJECT: High Lead Levels in Flint, Michigan – Interim Report

FROM: Miguel A. Del Toral
Regulations Manager, Ground Water and Drinking Water Branch

TO: Thomas Poy
Chief, Ground Water and Drinking Water Branch

The purpose of this interim report is to summarize the available information regarding activities conducted to date in response to high lead levels in drinking water reported by a resident in the City of Flint, Michigan. The final report will be submitted once additional analyses have been completed on pipe and water samples.

Following a change in the water source, the City of Flint has experienced a number of water quality issues resulting in violations of National Primary Drinking Water Regulations (NPDWR) including acute and non-acute Coliform Maximum Contaminant Level (MCL) violations and Total Trihalomethanes (TTHM) MCL violations as follows:

Acute Coliform MCL violation in August 2014
Monthly Coliform MCL violation in August 2014
Monthly Coliform MCL violation in September 2014
Average TTHM MCL violation in December 2014
Average TTHM MCL violation in June 2015

In addition, as of April 30, 2014, when the City of Flint switched from purchasing finished water from the City of Detroit to using the Flint River as their new water source, the City of Flint is no longer providing corrosion control treatment for lead and copper.

A major concern from a public health standpoint is the absence of corrosion control treatment in the City of Flint for mitigating lead and copper levels in the drinking water. Recent drinking water sample results indicate the presence of high lead results

in the drinking water, which is to be expected in a public water system that is not providing corrosion control treatment. The lack of any mitigating treatment for lead is of serious concern for residents that live in homes with lead service lines or partial lead service lines, which are common throughout the City of Flint.

In addition, following the switch to using the Flint River, the City of Flint began adding ferric chloride, a coagulant used to improve the removal of organic matter, as part of the strategy to reduce the TTHM levels. Studies have shown that an increase in the chloride-to-sulfate mass ratio in the water can adversely affect lead levels by increasing the galvanic corrosion of lead in the plumbing network.

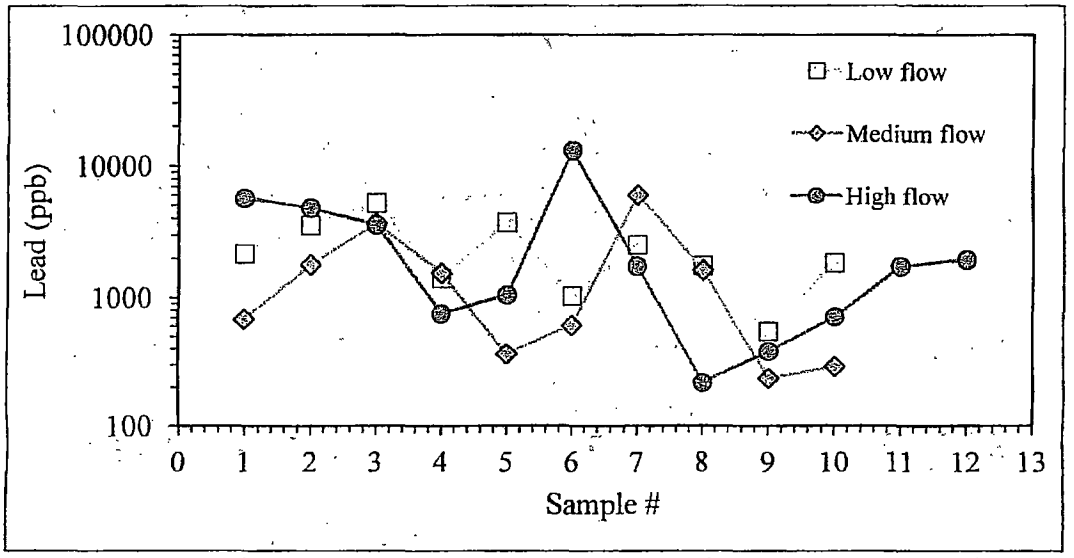
Prior to April 30, 2014, the City of Flint purchased finished water from the City of Detroit which contained orthophosphate, a treatment chemical used to control lead and copper levels in the drinking water. When the City of Flint switched to the Flint River as their water source on April 30, 2014, the orthophosphate treatment for lead and copper control was not continued. In effect, the City of Flint stopped providing treatment used to mitigate lead and copper levels in the water. In accordance with the Lead and Copper Rule (LCR), all large systems (serving greater than 50,000 persons) are required to install and maintain corrosion control treatment for lead and copper. In the absence of any corrosion control treatment, lead levels in drinking water can be expected to increase.

The lack of mitigating treatment is especially concerning as the high lead levels will likely not be reflected in the City of Flint's compliance samples due to the sampling procedures used by the City of Flint for collecting compliance samples. The instructions from the City of Flint to residents direct the residents to 'pre-flush' the taps prior to collecting the compliance samples. A copy of the instructions provided by the City of Flint to residents will be included in the final report.

The practice of pre-flushing before collecting compliance samples has been shown to result in the minimization of lead capture and significant underestimation of lead levels in the drinking water. Although this practice is not specifically prohibited by the LCR, it negates the intent of the rule to collect compliance samples under 'worst-case' conditions, which is necessary for statistical validity given the small number of samples collected for lead and copper under the LCR. This is a serious concern as the compliance sampling results which are reported by the City of Flint to residents could provide a false sense of security to the residents of Flint regarding lead levels in the water and may result in residents not taking necessary precautions to protect their families from lead in the drinking water. Our concern regarding the inclusion of 'pre-flushing' in sampling instructions used by public water systems in Michigan has been raised with the Michigan Department of Environmental Quality (MDEQ). The MDEQ has indicated that this practice is not prohibited by the LCR and continues to retain the 'pre-flushing' recommendation in their lead compliance sampling guidance to public water systems in Michigan. A copy of the MDEQ guidance will be included in the final report.

In the case of the Flint resident that contacted U.S. EPA (Ms. Lee-Anne Walters), the initial results from drinking water samples collected by the City of Flint in her home

for lead were 104 ug/L and 397 ug/L. The level of iron in the water also exceeded the capability of the measurement (>3.3 mg/L). The lead results were especially alarming given that the samples were collected using the sampling procedures described above, which minimize the capture of lead. When contacted by U.S. EPA Region 5, the MDEQ indicated that the lead was coming from the Walters' plumbing. Ms. Walters had previously indicated that all of the plumbing in the home was plastic.



Following the confirmation of the initial high lead results, U.S. EPA Region 5 conducted two visits to the Walters' home on April 27, 2015 and May 6, 2015. Based on an inspection of the plumbing and subsequent sampling conducted at the Walters' residence, it was determined that except for a few minor metallic connectors, all interior plumbing, including the pipes, valves and connectors are made of plastic certified by the National Sanitation Foundation (NSF) for use in drinking water applications. Subsequent sampling showed that the faucets in the home appear to be compliant with the new lead-free requirements and are also not the source for the high lead levels. Our inspection of the interior plumbing and analysis of follow-up sampling results demonstrate that the home plumbing network is not the source of the high lead levels found at the Walters' residence. The photographs and all sampling results will be included in the final report.

Based on the U.S. EPA inspection and documentation of the plastic plumbing at the Walters' residence, it was suspected that the high lead was being introduced into the Walters' home plumbing from outside the home, likely from a lead service line. Three portions of the service line were extracted during a subsequent trip on May 6, 2015 and sent for analysis, when the Walters' service line was replaced. Analyses performed to date indicate that a portion of the service line is made of galvanized iron pipe. Inspection of the remaining portion from the water main to the external shut-off valve confirmed that the portion from the water main to the external shut-off valve is a lead service line.

Ms. Walters has also provided U.S. EPA with medical reports on her child's blood lead testing indicating that the child had a low blood lead level (2 ug/dL) prior to the source water switch and an elevated blood lead level following the switch (6.5 ug/dL). Redacted copies of these reports will also be included in the final report.

Subsequent to the discovery of high lead levels in the Walters' drinking water, the water to the Walters' home was shut off on April 3, 2015. The water was briefly turned back on to collect additional samples on April 28, 2015. Since the water had stagnated for an extended period of time, the kitchen tap was flushed for 25 minutes the night before collecting the samples. Three sets of samples were collected at different flow rates (10 at low flow, 10 at medium flow and 10 at high flow).

The drinking water samples collected from the Walters' residence on April 28, 2015 contained extremely high lead levels, ranging in value from 200 ug/L to 13,200 ug/L (see below).

Sample results and graph are provided courtesy of Virginia Tech

Additional sample results from resident-requested samples have also shown lead levels in excess of the lead action level. As with the samples collected by the City of Flint for compliance, the resident-requested samples are also being collected using the 'pre-flushing', so the lead levels captured in these samples likely do not represent the worst-case lead levels in the water and the actual lead levels at these homes may be much higher.

Pending completion of the final report, my interim recommendations are as follows:

1. The U.S. EPA should follow up with the MDEQ and the City of Flint on the recommendation made by U.S. EPA to MDEQ on June 10, 2015 to offer the City of Flint technical assistance on managing the different water quality issues in Flint, including lead in the drinking water. Although there have been two written assessments regarding water quality and operational issues in Flint at the time of this report, they do not address lead in drinking water. The first is an Operational Evaluation Report (OER) produced in November 2014 by Lockwood, Andrews and Newnam, Inc. to assess the factors contributing to high Total Trihalomethane (TTHM) levels in Flint following the source change. The focus of this report is to identify potential causes and remedial actions for lowering TTHM levels. The second report (Water Quality Report) produced by Veolia for the City of Flint on March 12, 2015, is an assessment of Flint's water quality and operations which provides advice to the City of Flint primarily focused on TTHM control and other operational issues. Both reports were written prior to the recent discovery of high lead results in Flint drinking water. As such, the reports do not take into account the potential effects on lead levels in drinking water.

As previously mentioned, the City of Flint currently has no mitigating

Department of Utilities

FLINT WATER PLANT

Memorandum

To: Water Plant Personnel

From: Mike Glasgow
Utilities Administrator

Date: October, 22 2015

Subject: **Laboratory testing requirements for current water supply**

Due to the recent change in water supply, the drinking water testing for the water plant laboratory personnel has been adjusted. The testing has been arranged to reflect what was conducted in years prior to operation of the treatment plant from the river. There are a few additional items that have been included, and this schedule may be adjusted as necessary.

AM & PM PLANT RUN:

- Collect & analyze samples for chlorine residual and Coliform Bacteria in the morning and afternoon (at least 4 hours apart) from the following sites on plant grounds:
  Control Station # 2, Dort Well, Pump Station # 4, & Lab Tap

LAB TAP TESTING:

- Collect & analyze lab tap samples once daily for pH, fluoride, total hardness, alkalinity, non-carbonate hardness, calcium, magnesium, total phosphate, temperature and chloride.
- Collect & analyze 3 samples daily (at least 3 hours apart) for Turbidity.
- Collect & analyze 1 sample weekly for Heterotrophic bacteria.

DISTRIBUTION SAMPLING:

- Collect & analyze samples from the 10 distribution sites at least twice weekly for chlorine residual and coliform bacteria. A total of at 100 samples must be collected and analyzed each month, so in total, at least 10 sampling events should take place each month.
- Once weekly also test each distribution site for fluoride, total phosphate, and Heterotrophic bacteria.
- Once quarterly perform Water Quality Parameters (WQM) from the 25 distribution sites. Total phosphate will be a new addition to all the other parameters tested.
- Once quarterly collect Disinfection Byproduct samples (DBP) from 8 sites according to the current DBP schedule. Next sampling will take place the 3rd full week of November.
- Lead & copper sampling will be on going throughout the rest of the year, a detailed plan will be completed soon.

RIVER SAMPLING:

- When time permits, a river sample should be collected once weekly and analyzed for coliform bacteria, pH, fluoride, total hardness, alkalinity, non-carbonate hardness, calcium, magnesium, temperature, turbidity, and chloride.

Subject: Follow Up from our Aug. 4th meeting

Dear Ms. Walters,

I wanted to update you regarding our Department's findings related to questions raised during our meeting at the Governor's office on August 4. I apologize for the delay in getting back to you.

Lead and Copper Monitoring

Regarding Flint lead and copper compliance monitoring for the January – June 2015 period, the City has confirmed that all lead and copper samples collected throughout the City, whether routine sites or customer requests, were sent to the State of Michigan lab for analysis. Individual sample results are provided to the property owner within 30 days of receiving the lab results in accordance with the Michigan Safe Drinking Water Act (Public Act 399, 1976 Administrative Rule 410(5). Results from the State of Michigan lab are provided directly to our Office.

Staff have confirmed that the lead 90th percentile compliance calculation of 11 parts per billion is based on 69 samples that met the appropriate sampling location site criteria, and met the sample collection site and collection protocol requirements of the Safe Drinking Water Act for this monitoring period. A minimum of 60 samples were required for this monitoring period. As indicated during the meeting, the City's sampling for lead complies with the Action Level standard of 15 parts per billion, but based on the population served by the City and these results, the City will need to make a recommendation to the MDEQ on how they will fully optimize their corrosion control treatment. These next steps continue to follow the requirements of the Lead and Copper Rule.

Samples collected at your residence of 212 Browning Avenue were not included this compliance determination as you utilize a whole home filter. As stated in the Michigan Safe Drinking Water Act (Public Act 399, 1976 Administrative Rule 710a, Lead and Copper in tap water; monitoring requirements) "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment alters the water chemistry and water quality such that it is no longer representative of public water from the City's distribution system. Therefore, the City cannot use samples collected at your residence as part of its determination for public water system compliance with the lead or copper action level standard.

Sample Summary (samples taken at your residence)

For your information, we are providing the information that we've gathered regarding samples collected at your home. Our records indicate between February and June of this year there were six samples collected by either you or Mr. Mike Glasgow with the City of Flint, and submitted to the State Laboratory for analysis as follows:

February 11, Bathroom tap, collected at 10:20 AM by Mike Glasgow. This sample was analyzed for aesthetic metals (copper, iron, manganese, and zinc) which does not include lead analysis.

February 18, Kitchen tap, collected at 7:15 AM by you. This sample was analyzed for lead (104 parts per billion) and copper (non-detect).

February 25, Kitchen tap, collected at 10:26 AM by Mike Glasgow. This sample was analyzed for metals including lead. All results (including lead) were non-detect except for Barium 0.01 parts per million. The result for Barium was well below its maximum contaminant level of 2 parts per million.

March 3, Kitchen tap, collected at 6:00 AM by you. This sample was analyzed for lead (397 parts per billion) and copper (non-detect).

March 18, Kitchen tap, collected at 11:10 AM by Mike Glasgow. This sample was analyzed for lead (4 parts per billion) and copper (non-detect).

April 2, Pre-point of service, collected at 8:00 AM by you. This sample was analyzed for lead (707 parts per billion) and copper (110 parts per billion).

Lead Education/Outreach

As we discussed during the meeting, we support efforts to educate homeowners about the sources of lead in their private residence, provide guidance measures to reduce the potential for lead exposure, and provide information on resources for lead abatement. Along those lines, our Office has been in contact with the Department of Health and Human Services, Environmental Health Division, Healthy Homes Section and had some preliminary discussions about a public education and assistance campaign regarding household lead issues, guidance and abatement.

Lead monitoring by public water systems serves a dual purpose. The first purpose is to ensure the public water supply is adequately treating its water to address corrosion potential and help limit lead exposure. The second purpose is to inform homeowners about lead levels within their individual residence so that they can make educated choices regarding their own exposure risk.

pH Results

During the meeting concerns were also expressed regarding pH levels within customer plumbing systems. As you may know, pH has no associated contaminant level as it is simply a numeric scale used to specify the acidity or alkalinity of a solution. The City of Flint conducts daily monitoring of pH values on both its raw and finished (treated) water at the City's water treatment plant as part of its operations. The City is also required to conduct water quality parameter monitoring in the distribution system, which includes pH. Samples are analyzed in accordance with Standard Methods using properly calibrated analytical equipment. Results for pH from these samples are summarized below.

Since late April 2014 – June 2015, the following pH conditions were reported:

Water Treatment Plant – Finished Water plant tap pH range = 7.07 minimum to 9.9 maximum, overall average 7.7, measured daily. We believe the 9.9 is a one- time anomaly from softening treatment.

Distribution System – Water Quality Parameters taken from 25 sample sites located throughout and monitored quarterly
July – Sept. 2014: pH 7.71 average, range 7.56 – 7.86
Oct. – Dec. 2014: pH 7.88 average, range 7.62 – 8.10
Jan. – March 2015: pH 7.81 average, range 7.60 – 7.99
April – June 2015: pH 7.63 Average, range 7.48 – 7.80

In addition, the City's treated water contains alkalinity, which is a measurement of the buffering capacity of water to resist a change in pH. As you can see from the water quality parameter monitoring results above there has been very little change in pH within the City's distribution system. The pH levels described within customer site piping or premise plumbing systems are believed to be the result of onsite treatment and not representative of water quality shown to be occurring in the public water supply system.

Consumer Confidence Report

Finally, there was confusion during the meeting regarding the City's annual water quality report, the Consumer Confidence Report which we have since been able to clarify.

The City of Flint issued two separate Consumer Confidence Reports (CCR's) in 2015 covering the water quality data from 2014. One report was for the period of January – April 2014 when the City was obtaining water from Detroit (DWSD). And a second report was for the period April – December 2014 when the City was using the Flint River and its own Water Treatment Plant.

The CCR for DWSD water was mailed to customers in June. The Flint River based CCR was mailed to customers in mid-July, delayed due to issues with the printing contractor. We agree that having two separate reports caused confusion. We are working with the City to ensure both reports are posted to the City's website and both are made available when requested by customers. Should the City choose to create separate CCR's during the year that the City of Flint connects to the Karegnondi Water Authority we will work with the City to provide more clarity and try to have all material included in a single mailing.

The DWSD based CCR is the one community members had at the meeting, while the DEQ brought a copy of the Flint River based CCR. As separate and distinct sampling was done under each source, this explains the discrepancy in the values and monitoring periods being reported in the respective CCR's.

We appreciate your interest in these matters and hope this has addressed many of the questions brought up during our meeting. I would like to provide this information to both Dr. Sullivan and Ms. Mayes, but I do not have their contact information. I'm hoping you can share this with them and any others that may be interested.

Sincerely,

Liane J. Shekter Smith, P.E., Chief
Office of Drinking Water and Municipal Assistance
Michigan Department of Environmental Quality
517-284-6543

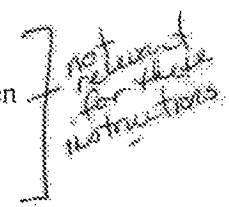
Flint Drinking Water Task Force (FTF 15-2)

Task Force Comments on Flint's Residential Drinking Water Lead & Copper Sampling Instructions

EPA received the draft of Flint's Residential "Drinking Water Lead & Copper Sampling Instructions" for comment from Jim Sygo, MDEQ, on November 13, 2015. Below are comments from EPA's Flint Safe Drinking Water Task Force.



General

It should be clearly stated that these sampling instructions are for LCR compliance monitoring – from now on without the pre-flushing.

Specific Comments

1. The Task Force agrees with the removal of pre-flushing.

2. In the "Dear Resident" cover paragraph, we suggest changing the text "...provide a more accurate gauge of the amount of lead exposure...", because though this is a much better representation of the water intended to be captured by the LCR, it DOES NOT REPRESENT EXPOSURE. We suggest: "The new method is designed to provide a more accurate gauge of lead levels at the tap under normal household use using the current regulatory sampling requirements." We recommend that when the residents are sent their results, that it includes an explanation that the result does not represent lead exposure and that first draw samples have been found to underestimate lead levels in direct contact with a lead service line. It is recommended that customers continue to use the water filters that have been provided to minimize lead exposure.

3. Item 1 needs to require that samples be unfiltered/untreated. Samples may be taken from either a kitchen or bathroom faucet commonly used for drinking, provided the faucet used has no filter attached or the filter has been bypassed. Instructions need to be provided on how to bypass the faucet mount filters that have been distributed. Other home treatment devices must be bypassed too. If the resident has questions about how to bypass a treatment device, they should call the water supply.

Depending on which Flint and MDEQ feel would be more easily understood by residents, the following are two potential alternatives to current Item 1 that would ensure only untreated/unfiltered samples are collected:

Alternative 1

Select an unfiltered/untreated faucet in the KITCHEN or BATHROOM that is commonly used for drinking. DO NOT use a faucet that has a filter attached to it unless you bypass the filter. DO NOT use a faucet that is connected to a home water treatment device (like a water softener, iron filter, reverse osmosis) unless you bypass the home water treatment device. DO NOT sample from a laundry sink or a hose spigot as these samples cannot be used by your utility.

Flint Drinking Water Task Force (FTF 15-2)

Alternative 2

1: Does the kitchen tap have a faucet mount filter or a reverse osmosis unit on it? If NO, go to 1a. If YES, go to 1b.

a) Select a faucet in the KITCHEN or BATHROOM that is commonly used for drinking. DO NOT use a faucet that is connected to a home water treatment device (like a water softener, iron filter, reverse osmosis) unless you bypass the home water treatment device. DO NOT sample from a laundry sink or hose spigot as these samples cannot be used by your utility.

b) Select a BATHROOM faucet that is commonly used and does not have a treatment device attached to it. DO NOT use a faucet that is connected to a home water treatment device (like a water softener, iron filter, reverse osmosis) unless you bypass the home water treatment device. DO NOT sample from a laundry sink or hose spigot as these samples cannot be used by your utility.

There should be a question on the form asking if the resident has installed a faucet mount filter, so this can be recorded (see suggested change to 4C in comment 6 below). [Note: Installing the faucet mount filter would require the removal of the faucet's aerator. Does MDEQ know if the faucet mount filters being used have an aerator screen in the unit?]

4. On Item 2, the LCR currently has no upper limit on standing time, and we have published research data showing that under normal usage conditions, lead release may not have even reached equilibrium at 12 hours. The minimum of 6 hours stagnation time is used rather than a longer time so as not to discourage people from volunteering to take lead and copper samples. Therefore, for consistency with the text of the rule, we recommend just leaving it at "Wait at least 6 hours..." We understand it's not useful to collect from totally inappropriate conditions, such as vacant houses and immediately after extended vacations, but the introductory paragraph clarifies that it represents the water they would "typically drink." If it is necessary to have a maximum stagnation time, then we recommend that you use a maximum of 24 hours which is consistent with the approach that was discussed with the National Drinking Water Advisory Council Working Group as an option in 2014.

5. Again in Item 2, there must be an instruction to not use the water anywhere in the house during the stagnation period. Depending on the house plumbing configuration and pipe inside diameter (ID), using other taps, toilets, bathtubs, dishwashers, etc. may draw water from the zone of plumbing captured in a 1 liter sample. That will usually cause a low bias to the results, by bringing in fresh water. Only rarely is LSL water brought precisely into that volume captured by the sample. So, instructions need to be clear about no water use in the house.

6. Recommended language for Item 4C (for inventory purposes and to verify that the sample was unfiltered/untreated):

- Does this faucet have a faucet mount filter such as the lead filters provided to the community? Yes/No

    - If Yes, was the faucet mount filter bypassed during the sampling? Yes/No
- Is this faucet connected to a reverse osmosis unit? Yes/No
    - If Yes, was the reverse osmosis unit bypassed during the sampling? Yes/No
- Does the house have a home treatment device, such as a water softener or iron removal device or any other type of water treatment? Yes/No
    - If Yes, please describe _____
    - Was this home treatment device in use during sampling or the day before sampling? Yes/No

7. In our experience, and in the experience of other utilities who try to use the LCR monitoring data to assess effectiveness of their treatment for the control of lead release, the form should ask for the resident to note the approximate time of last use of that faucet from which the sample is taken, as well as the time the bottle is filled. Since the typical 6-12 hour period is not really at equilibrium in most cases, soluble lead could differ by a substantial amount from a 6 hour standing sample to, say, a 10 or 12 hour standing sample. When interpreting the data, that is good to know.

8. Not covered by the questions, but a recommendation we need to make, is to suggest that there is good research evidence that higher flow rates are the typical conditions for when consumers turn their faucets on. More particulate lead can be eroded in some circumstances, so using a wide-mouth bottle allows a much more representative sample to be collected for the conditions of consumer use. Our understanding is that MDEQ furnishes the bottles, so we recommend to change the type of bottle provided. The furnished bottles with the smaller mouth can only be filled without splashing at flow rates that are much lower than what someone normally uses to fill glasses, coffee pots, pots for cooking, etc.

These changes should be made to all of the sampling recommendations or instructions from MDEQ to all systems, not just Flint.

Michigan Department of Community Health

Flint Water Lead Communication Plan

September 9, 2015

Presented by:

MDHHS-DEH Toxicology & Response Section

Plan Overview

Project: Flint Water Lead

Name of Campaign: To be Determined (e.g. Lead us to Water: Flint Clean Water)

Objective

The Michigan Department of Health & Human Services has a mission to protect, preserve, and promote the health and safety of the people of Michigan with particular attention to providing for the needs of vulnerable and under-served populations. The residents of Flint currently perceive problems related to the usage of the Flint River as their temporary water source until a pipeline is completed which will bring water from Lake Huron. Problems – both substantiated and unsubstantiated included excess TTHM, discolored water, and high levels of lead in tap water. These problems have given rise to a well-organized community group Water You Fighting For (wateryoufightingfor.com) and has gotten the attention of water activists/researchers from Virginia Tech University (flintwaterstudy.org).

Given there is no safe level of lead for young children, a public health outreach campaign to inform the public of the sources of lead in their community is recommended. MDHHS will promote collaboration between the City of Flint, the County Health Department, community members, and other interested parties to halt human exposure of lead through development and proactive delivery of scientifically accurate information delivered in multiple formats at a literacy level that is accessible to all.

Background

Drinking water analytical reports find that the water meets the federal drinking water standards and is safe for public consumption. The aesthetic quality of the water, which may make the water unappealing to drink or use, does not make the water unsafe. Poor aesthetic quality, if true, will be a barrier to conducting an effective public health outreach campaign.

Lead is not found to be elevated in the drinking water at the source; however, citizens have reported high lead levels in their tap water. Sources of lead to the tap water are likely from lead piping or solder in or entering the home. Lead piping and solder are sources that the home-owner needs to know how to address. Additionally, older homes (pre-1978) can have lead containing paint and homes near historic high-traffic areas can have elevated lead levels in soil.

Target Markets

- Citizens of Flint who use Flint City Water
- Citizens of Flint who live in homes built in 1987 or before
- Citizens of Flint who are pregnant or have children living in the home that are 6 or under

Message Summary

- There are personal actions individuals can take to prevent exposure to lead.
- Lead exposure does not just occur through water.
- You can be tested for blood lead levels to determine if you or your children been exposed.
- There are resources available to assist with remediation.

Call to Action

Exposure to lead through pipes, paint, and soil are preventable. There are steps people can take to be proactive in preventing their exposure and potential health issues. MDHHS notes that this problem is also not limited to Flint. This campaign will be created and piloted with the City of Flint, but may be expanded statewide.

Project Plan

Public Meetings –

- Begin with small groups to identify key stakeholders
- Plan larger meeting addressing
    - the lifespan of water from source to treatment center to home
    - how people can identify if their home may be affected
    - what the VTU results really mean
    - what can be done on an individual, city, and state level

e-Toolkits, Social Media & Print Outreach

- Compile existing information on being lead-safe
- Create easily shared infographics – what can be done, what are signs and symptoms
- Create brochures about health effects of lead

http://www.mlive.com/news/flint/index.ssf/2015/09/new_testing_shows_flint_water.html

- On Monday, Aug. 31, the researchers reported 42 percent of 120 initial samples from Flint had lead levels that were more than 5 parts per billion, "which suggests a serious lead-in-water problem, according to our experience and criteria."
- The EPA requires water systems like Flint's to collect tap samples from sites that are more likely to have plumbing materials containing lead.
- If more than 10 percent of samples exceed 15 ppb, then water systems are required to take action, including steps to optimize corrosion control treatment.
- "The city of Flint has offered free and independent testing to residents since spring, and I encourage people to use this service if they have questions," Walling's statement said.
- Edwards, a professor of civil and environmental engineering, said the elevated lead levels he has seen in Flint tap water are tied to a corrosive water source that contains about eight times more chloride than Detroit water does.
- "Chloride is generally considered to be very corrosive to iron. For instance, chloride present in road salts applied in the winter causes iron in cars and bridges to rust," the Virginia Tech team's website says.
- "This could be a huge public health problem. ... The Flint water just ate the pipe up," Edwards said of the testing he has overseen so far.
- "If it were me, I would not be using (Flint River water) for cooking or drinking unless I had it tested for lead," said Edwards, who previously mounted a six-year campaign that succeeded in forcing the U.S. Centers for Disease Control and Prevention to admit it had misled the public about the risk of lead in the Washington, D.C., area's drinking water, according to The

Washington Post.

- Since the switch, the city has been plagued by issues such as water main breaks and boil water advisories because of bacteria and has been in violation of the Safe Drinking Water Act because of high levels of total trihalomethanes (TTHM), a byproduct of chlorinating river water.
- The Rev. Allen Overton, who hand-delivered petitions to Walling on Monday, asking that city officials reconnect the Flint water system to Detroit, said Wednesday that the Virginia Tech experiment is more evidence Flint is not using the best quality of water available.
- "We have a major health issue here, (and) they are not being honest with the citizens of Flint," Overton said.

Flint Water Petition:

https://secure3.convio.net/fww/site/Advocacy;jsessionid=7266B35978FAD2EFBD3A57D87D5085AB.app334b?pagename=homepage&page=UserAction&id=2199&autologin=true&s_src=blg&s_subsrc=070915a

Dear [Flint Mayor Dayne Walling and Flint City Council],

Water is a basic human right. The United Nations General Assembly recognizes that access to safe drinking water and sanitation are essential to the realization of all human rights.

In 2014, Flint's emergency manager disconnected the city from the Detroit Water and Sewerage Department (DWSD) and started providing residents with water from the Flint River. Since that time, residents have been struggling to maintain access to a clean, safe drinking water supply.

Residents of Flint report having tap water with high levels of copper, lead, THMs (chemicals that result when chlorine mixes with organic matter), tin, lime and iron. The water is often brown or bluish-green in color and contains sediment. As a result, people are experiencing symptoms including hair loss, lead poisoning and diseases related to consuming high levels of copper (to name a few).

The Flint River clearly is not a safe, reliable source for the city's drinking water. It was as easy as pushing a button to disconnect from DWSD; it's time to push the button again, reconnecting Flint to DWSD and providing Flint residents with the clean, safe water they deserve.

Please reconnect Flint to the Detroit Water and Sewerage Department immediately and make water safe and clean for all.

Sincerely,
[Your Name]
[Your Address]
[City, State ZIP]

Washington DC

- Sources of lead in drinking water

- **Lead service pipe**
  In the U.S., lead service pipes were installed until the mid-1950s. Older properties may still have lead service pipes, which connect the water main in the street to household plumbing. The service pipe is owned by the property owner. Under certain conditions, DC Water is authorized to repair, maintain or renew the portion of the service pipe in public space. The maintenance of the portion of the service pipe on private property is the exclusive responsibility of the property owner. A "partial" lead service pipe replacement is where a portion of the service pipe is replaced, but a portion made of lead remains in public or private space.

  Lead service pipes were installed until the mid-1950s.

- **Lead solder**
  This connects pipes in household plumbing. In 1987, lead solder was banned from use in household plumbing. If your house was built before 1987, your plumbing may have lead solder.

- **Brass faucets, valves or fittings**
  Almost all faucets, valves and fittings have brass components. Until 2014, brass faucets and fittings sold in the U.S. and labeled "lead-free" could contain up to eight percent lead. Effective January 2014, the Reduction of Lead in Drinking Water Act specifies that these materials may not contain more than 0.25 percent lead.

- **Galvanized iron pipes**
  Household galvanized pipes are old, corroded pipes that were installed in many homes before the 1960s. These pipes can release lead in water if the property has, or previously had, a lead service pipe. Galvanized pipes are made with a protective layer of zinc. However, the zinc layer erodes over time and results in corrosion. When lead is released from a lead service pipe and passes through galvanized plumbing (particularly over decades of use), lead can accumulate on the inside, corroded walls of this plumbing.

  Lead release from galvanized pipes can vary from home to home and can continue to occur even after a lead service pipe is replaced. Galvanized pipes can cause other water quality problems, such as low water pressure and discolored water. For additional information on household plumbing, click here.

Subject: Water Quality Optimization Strategy

Howard,

As Mike Prysby and I mentioned during our phone call earlier today, the City should be taking action to optimize water quality in the City's distribution system which will in turn provide the City's water customers with water quality that helps limit the potential for legionella occurrence in premise plumbing. It is recognized that contraction of Legionnaires' Disease is not from ingestion of potable water and not regulated under Safe Drinking Water Act requirements. Further, there is currently no direct evidence of legionella in the City's public water system. However, actions by the City of Flint water system can help minimize the potential for an outbreak in customer plumbing systems.

These actions include the following:

- Water main pigging and flushing to remove biofilm, tuberculation, and sediment throughout the distribution system. Failure to remove such material will limit the effectiveness of any disinfectant. Pigging is the preferred process and equipment can be obtained at minimal cost. As the growth range for legionella starts at 68 degrees F, conducting this work as soon as possible in the spring and early summer with cooler temperatures would help reduce the potential for formation under warmer water conditions.

- Maintain pH levels of 7.2-7.8 in finished water and distribution system when possible to maximize the disinfection and oxidation potential of the hypochlorous acid residual (versus the less potent hypochlorite ion). Any optimized corrosion control plan practices regarding pH levels must be taken into consideration.

- Maintain a minimum free chlorine residual of 0.5 mg/L throughout the distribution system when possible. Continuous residual at this level has been shown to be effective in control of legionella. (This will need to be balanced with requirements to limit TTHM formation and comply with the TTHM standard.)

- Continuous operation and optimization of the ozone treatment equipment to treat raw source water. Ozone is highly effective in the destruction of legionella bacteria.

- Conduct routine monitoring for legionella bacteria at the water treatment plant tap and at locations in the distribution system. Note: sample locations must take water directly off the main and not be from premise plumbing systems. Distribution locations could include storage tank inlets or pumping stations. Monitoring at the WTP plant tap would demonstrate removal of any legionella present in raw source water. A private laboratory that specializes in water sample analysis for legionella would need to be used.

- Optimize water treatment plant operation for pathogen reduction under surface water treatment rule requirements. Optimizing the removal for similar pathogens can help reduce the potential for legionella.

A conference call with City staff would probably be best to facilitate further discussions of these actions in more detail. Mike and I can make ourselves available this week to discuss and answer any questions.

MEMORANDUM

SUBJECT: Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems

FROM: Peter C. Grevatt, Director
Office of Ground Water and Drinking Water

TO: EPA Regional Water Division Directors, Regions I-X

This memorandum addresses certain concerns raised about the application of the 1991 Lead and Copper Rule, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. These concerns have been raised most recently in regard to the drinking water system in Flint, Michigan, where the water system was disconnected from the Detroit Water and Sewerage Department, which provided corrosion control treatment for Lake Huron source waters, and instead began distributing water from the Flint River. This type of situation rarely arises and the language of the LCR does not specifically discuss such circumstances. After reviewing the rule with our Office of General Counsel, it appears that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation, which may have led to some uncertainty with respect to the Flint water system. This memorandum clarifies how the LCR applies to this situation and eliminates the uncertainty for water systems and primacy agencies that may face these circumstances in the future.

It is important for large systems and primacy agencies[1] to take the steps necessary to ensure that appropriate corrosion control treatment is maintained at all times, thus ensuring that public health is protected. This memorandum focuses on those steps and clarifies, on a prospective basis, how EPA interprets the LCR corrosion control requirements and how primacy agencies should apply these requirements to large public water systems before, during and after making a significant change in source water, including switching from purchased water to a new source.

Under the LCR, all large systems (those serving more than 50,000 persons), whether purchasing water or not, must have completed a series of steps to either optimize the corrosion control treatment or be deemed to have optimal corrosion control treatment (OCCT) by 1998. 40 CFR 141.81. Key steps for

[1] The term "primacy agency" refers to the State, tribe or U.S. Environmental Protection Agency regional office having jurisdiction over, and primary enforcement responsibility for, a given public water system.

optimizing corrosion control include monitoring, corrosion control studies, installation of treatment, follow-up sampling and specification by the primacy agency of water quality parameters (WQPs) for monitoring corrosion control. The LCR requires any large system that has met the OCCT requirements through the installation of corrosion control treatment to continue operating and maintaining the treatment and to continue meeting the WQPs established by the primacy agency. 40 CFR 141.81(b) and 141.82(g). Systems deemed to have OCCT without the installation of corrosion control treatment are not subject to this requirement. However, they are required to notify the primacy agency in writing of any upcoming changes in treatment or source and request that the primacy agency modify its determination of the OCCT and WQPs applicable to the system. The primacy agency must then review and approve the change and designate OCCT and WQPs prior to its implementation by the system. 141.81(b)(3). Similarly, systems subject to reduced monitoring or monitoring waivers must notify the primacy agency of any upcoming changes in treatment or source and the primacy agency must subsequently review and approve it. EPA recommends that systems that are not subject to a notification requirement also notify the primacy agency prior to the addition of a new source or treatment and request the primacy agency to modify its determination of the optimal corrosion control and WQPs applicable to the system.

Due to the unique characteristics of each PWS (e.g., source water, existing treatment processes, distribution system materials) it is critical that public water systems, in conjunction with their primacy agencies and, if necessary, outside technical consultants, evaluate and address potential impacts resulting from treatment and/or source water changes. It is also critical for public water systems to conduct ongoing monitoring to ensure compliance with OCCT prior to, during and after a source or treatment change. The rearrangement of a system's existing configuration may trigger the need for OCCT adjustments and establishment of appropriate WQPs. Primacy agencies should work with systems that plan to disconnect from a supplier that had installed corrosion control treatment to determine the OCCT for the new source and establish WQPS for that treatment instead of using the OCCT and WQPs established for the previous source. This will allow a system that ceases to purchase treated water to stay in compliance with any applicable requirements pertaining to OCCT and ensure protection of public health during and after the change in source. EPA has developed a guidance manual[2] specifically focusing on evaluation of corrosion control treatment options and optimization of full-scale treatment to assist water systems and primacy agencies with these efforts. EPA is currently preparing an updated version of the manual, which we anticipate will be released in February 2016.

The key to identifying and mitigating potential problems is to ensure effective collaboration between the public water system and the primacy agency. Corrosion control treatment can come in many forms. For this reason, it is important to conduct a system-wide assessment prior to any source water and/or treatment modifications and to identify existing or anticipated water quality, treatment or operational issues that may interfere with or limit the effectiveness of corrosion control treatment optimization or re-optimization.

If you have additional questions or concerns, please contact me or have your staff contact Maria Lopez Carbo, Chief of the Protection Branch, in the Office of Ground Water and Drinking Water, at lopez-carbo.maria@epa.gov.

STATE OF MICHIGAN

September 10, 2015

Michigan Department of Environmental Quality
Executive Division
DEQ Director: Dan Wyant
P.O. Box 30473
Lansing, MI 48909-7973

Director Wyant,

In light of recently released findings by the American Civil Liberties Union, independent researchers and a troubling interim U.S. Environmental Protection Agency memo from June, we are requesting additional answers about the safety and treatment of the City of Flint's water.

Several disturbing points have been raised and we have a number of urgent questions, including:

- **When did the MDEQ become aware of the June 24, 2015, interim EPA memo and whom was it shared with?**
  - Which Flint city officials also received this information?
  - Why was the memo not immediately shared with the public?
  - What response did MDEQ have to the EPA concerns raised in the memo?
  - Were any actions taken by the MDEQ as a result of the issues mentioned in the memo?
  - What steps, if any, were taken to determine the validity of the Virginia Tech study?

- **Please explain why the pre-flushing method of sampling was used in this instance.**
  - Is it the same method that is applied to all sampling or does the agency have the discretion to decide?
  - Who is responsible for making the decision to pre-flush?
  - The EPA memo references the Lead Copper Rule requirement that systems greater than 50,000 users maintain "corrosion control treatment." As the regulator, why did the MDEQ choose not to enforce that standard?
  - The EPA recommends allowing water to rest for at least six hours, but no more than 12 hours, before taking a sample. On MDEQ's Web site, it suggests flushing the line for five minutes before the six-hour rest. How did the department arrive at this method?

- According to a July 9, 2015, article on DeadlineDetroit.com, "Scary: Leaded Water and One Flint Family's Toxic Nightmare,"

  "'The EPA offered Flint officials the use of agency experts to help get the situation under control,' said Del Toral, but added that, to his knowledge, the city has so far declined all help.

  LeeAnne Walters said that when she asked why city officials weren't taking the EPA's offer of assistance, she was told, "We don't need it."

STATE OF MICHIGAN

Flint spokesman Lorenz, on the other hand, maintained "the city continues to work closely with the MDEQ and the EPA Regional Office."

- Who refused the EPA's offer of expert assistance and why?

- **Is the damage done to the pipes (as described in the EPA report) accurate?**
  - If yes, will damaged pipes continue to leach lead or will properly treated water safely reach consumers?
  - What is the plan and timeline to address it?

- **And most importantly, what can be done immediately to ensure safe, affordable drinking water for the citizens of Flint?**

Many of the decisions that led to the current situation occurred while a state-appointed manager was in control and MDEQ personnel were consulted about testing methods and how to address the situation. In addition, MDEQ also encouraged the method of water testing used by Flint officials. We believe that there is a heightened obligation by the state to make this right.

Due to the serious public health threats of this situation, we respectfully request a response to these matters by Monday, September 14, 2015.

We will do our best to accommodate meeting requests, if necessary, but would appreciate written responses to the above questions so that we can make informed decisions swiftly to address these serious concerns.

Sincerely,

Jim Ananich

Flint WTP 399 Permitting History – DRAFT

June 26, 2013

Meeting at WTP with Flint and KWA officials
Reviewed current WTP operations and upcoming test run
Discussed short-term/long term objectives
- WTP hydraulics
- Treatment goals
- Residuals
- Electrical redundancy
- Job duties

GCDC/Flint emergency interconnect

July 10, 2013

Visit to WTP to observe treatment plant test-run
Plan to introduce softening in this run
Plan for meeting with consultant to discuss additional WTP improvements needed for short term and long term op.

August 2013 – Received proposed scope of upgrades to the Flint WTP, based from the July 2011 report

August 27, 2013

Meeting at WTP with consultant to discuss scope of upgrades needed for both phases – Phase 1 (short term op. from Flint River) and Phase 2 (long-term op. from KWA)
Engineering design for specific improvements: 30-day supply, ele. Redundancy, new pumps/controls, lime sludge disposal options, additional disinfection, piping changes.

Leads to developing draft plans and specs

Nov 5, 2013

Meeting with city and consultant to discuss electrical redundancy and lime sludge disposal in more detail. Permitting of lime sludge disposal with the need to

upgrade the Bray Road lagoon site under the Act 399 permit was also discussed. Meeting with EM set for the following week.

Nov 13, 2013

EM pre-meeting - draft plans/specs for WTP upgrades are being prepared
Discussed timing of review/comments/ issuance of final plans – CP and construction scheduling. 2 permits to be issued (WTP, lime sludge disposal at Bray Road) Improvements include 30-day chem storage, midpoint CL2, electrical upgrades, high service pumping improvements, lime sludge disposal.

Meeting with EM –

Final approval to use WTP for continuous operation is based on permit issuance
Design/plans/bids to be submitted to DEQ
Separate permits to cover interim improvements (River) and permanent improvements (River and KWA).

Jan 2014 – March 2014

Draft plans/specifications – final plans/specifications submitted to DEQ for review, comment, and approval.

2/27/14 – DEQ provides comments to consultant on draft WTP submittal
3/19/14 – DEQ provides second set of comments to consultant of revised WTP improvements submittal
3/21/14 – DEQ provides comments to consultant on Bray Road sludge Lagoon submittal
4/3/14 - DEQ provides final comments to facilitate submittal of plans and specs acceptable for issuance of Act 399 permit

3/31/14

Meeting with consultant in Lansing to discuss last minute revisions to address storage of lime sludge at the Bray Road lagoon.
Discussed WTP project schedule, timing of work following issuance of Act 399 permit, operational oversight (number of operators/shifts). Potential start-up date. Confirm delivery of final plans/specs. Preparation of new monitoring schedule.

4/8/14 –

Act 399 permit issued for the WTP improvements and the Bray Road sludge lagoon upgrades.

PERMIT APPLICATION FOR WATER SUPPLY SYSTEMS

(CONSTRUCTION - ALTERATION - ADDITION OR IMPROVEMENT) AS DESCRIBED HEREIN

Required under the Authority of 1976 PA 399, as amended

This application becomes an Act 399 Permit only when signed and issued by authorized Michigan Department of Environmental Quality (DEQ) Staff. See instructions below for completion of this application.

1. **Municipality or Organization, Address and WSSN** that will own or control the water facilities to be constructed. This permit is to be issued to: **WSSN:**	Permit Stamp Area (DEQ use only)	
2. **Owner's Contact Person** (provide name for questions): Contact: Title: Phone:		
3. **Project Name** (Provide phase number if project is segmented):	4. **Project Location** (City, Village, Township):	5. **County** (location of project):

ISSUED UNDER THE AUTHORITY OF THE DIRECTOR OF THE DEPARTMENT OF ENVIRONMENT QUALITY

cc:

Issued by: _____

Reviewed by: _____

☐ **If this box is marked see attached special conditions.**

Instructions: Complete items 1 through 5 above and 6 through 21 on the following pages of this application. Print or type all information except for signatures. Mail completed application, plans and specifications, and any attachments to the DEQ District Office having jurisdiction in the area of the proposed construction.

Please Note:

a. This **PERMIT** only authorizes the construction, alteration, addition or improvement of the water system described herein and is issued solely under the authority of 1976 PA 399, as amended.
b. The issuance of this **PERMIT** does not authorize violation of any federal, state or local laws or regulations, nor does it obviate the necessity of obtaining such permits, including any other DEQ permits, or approvals from other units of government as may be required by law.
c. This **PERMIT** expires two (2) years after the date of issuance in accordance with R 325.11306, 1976 PA 399, administrative rules, unless construction has been initiated prior to expiration.
d. Noncompliance with the conditions of this permit and the requirements of the Act constitutes a violation of the Act.
e. Applicant must give notice to public utilities in accordance with 1974 PA 53, (MISS DIG), being Section 460.701 to 460.718 of the Michigan Compiled Laws, and comply with each of the requirements of that Act.
f. All earth changing activities must be conducted in accordance with the requirements of the Soil Erosion and Sedimentation Control Act, Part 91, 1994 PA 451, as amended.
g. All construction activity impacting wetlands must be conducted in accordance with the Wetland Protection Act, Part 303, 1994 PA 451, as amended.
h. Intentionally providing false information in this application constitutes fraud which is punishable by fine and/or imprisonment.
i. Where applicable for water withdrawals, the issuance of this permit indicates compliance with the requirements of Part 327 of Act 451, Great Lakes Preservation Act.

6. **Facilities Description** – In the space below provide a detailed description of the proposed project. Applications without adequate facilities descriptions **will be returned**. SEE EXAMPLES BELOW. Use additional sheets if needed.

EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES – EXAMPLES	
Water Mains	500 feet of 8-inch water main in First Street from Main Street north to State Street. OR 250 feet of 12-inch water main in Clark Road from an existing 8-inch main in Third Avenue north to a hydrant.
Booster Stations	A booster station located at the southwest corner of Third Avenue and Main Street, and equipped with two, 15 Hp pumps each rated 150 gpm @ 200 feet TDH. Station includes backup power and all other equipment as required for proper operation.
Elevated Storage Tank	A 300,000 gallon elevated storage tank located in City Park. The proposed tank shall be spherical, all welded construction and supported on a single pedestal. The tank shall be 150 feet in height, 40 feet in diameter with a normal operating range of 130 – 145 feet. The interior coating system shall be ANSI/NSF Standard 61 approved or equivalent. The tank will be equipped with a cathodic protection system, and includes a tank level control system with telemetry.
Chemical Feed	A positive displacement chemical feed pump, rated at 24 gpd @ 110 psi to apply a chlorine solution for Well No. 1. Chlorine is 12.5% NaOCL, ANSI/NSF Standard 60 approved and will be applied at a rate of 1.0 mg/l of actual chlorine.
Water Supply Well	Well No. 3, a 200 foot deep well with 170 feet of 8-inch casing and 30 feet of 8-inch, 10 slot screen. The well will be equipped with a 20 Hp submersible pump and motor rated 200 gpm @ 225 feet TDH, set at 160 feet below land surface.
Treatment Facilities	A 5 million gpd water treatment plant located at the north end of Second Avenue. The facility will include 6 low service pumps, 2 rapid mix basins, 4 flocculation/sedimentation basins, 8 dual media filters, 3 million gallon water storage reservoir and 6 high service pumps. Also included are chemical feed pumps and related appurtenances for the addition of alum, fluoride, phosphate and chlorine.

General Project Information – Complete all boxes below.

7. Design engineer's name, engineering firm, address, phone number, and email address:	8. Indicate who will provide project construction inspection: ☐ Organization listed in Box 1. ☐ Engineering firm listed in Box 7. ☐ Other - name, address, and phone number listed below.

9. Is a basis of design attached?
☐YES ☐NO

If no, briefly explain why a basis of design is not needed.

10. Are sealed and signed engineering plans attached?
☐YES ☐NO

If no, briefly explain why engineering plans are not needed.

11. Are sealed and signed construction specifications attached?
☐YES ☐NO

If specifications are not attached, they need to be on file at DEQ.

12. Were Recommended Standards for Water Works, Suggested Practice for Water Works, AWWA guidelines, and the requirements of Act 399 and its administrative rules followed?
☐YES ☐NO

If no, explain which deviations were made and why.

13. Are all coatings, chemical additives and construction materials ANSI/NSF or other adequate 3rd party approved?
☐YES ☐NO

If no, describe what coatings, additives or materials did not meet the applicable standard and why.

14. Are all water system facilities being installed in the public right-of-way or a dedicated utility easement? (For projects not located in the public right-of-way, utility easements must be shown on the plans.)
☐YES ☐NO

If no, explain how access will be obtained.

15. Is the project construction activity within a wetland (as defined by Section 324.30301(d)) of Part 303, 1994 PA 451?
☐YES ☐NO

If yes, a wetland permit must be obtained.

16. Is the project construction activity within a 100-year floodplain (as defined by R 323.1311(e)) of Part 31, 1994 PA 451, administrative rules?
☐YES ☐NO

If yes, a flood plain permit must be obtained.

17. Is the project construction activity within 500 feet of a lake, reservoir, or stream?
☐YES ☐NO

If yes, a Soil and Erosion Control Permit must be obtained or indicate if the owner listed in box 2 of this application is an Authorized Public Agency (Section 10 of Part 91, 1994 PA 451) ☐ Owner is APA.

18. Will the proposed construction activity be part of a project involving the disturbance of five (5) or more acres of land?
☐YES ☐NO

If yes, is this activity regulated by the National Pollutant Discharge Elimination System storm water regulations?
☐YES: NPDES Authorization to discharge storm water from construction activities must be obtained.

☐NO: Describe why activity is not regulated:

Please call 517-241-8993 with questions regarding the applicability of the storm water regulations.

19. Is the project in or adjacent to a site of suspected or known soil or groundwater contamination?
☐YES ☐NO

If yes, attach a copy of a plan acceptable to the DEQ for handling contaminated soils and/or groundwater disturbed during construction. Contact the local DEQ district office for listings of Michigan sites of environmental contamination.

20. IF YOU ARE A CUSTOMER/WHOLESALE/BULK PURCHASER, COMPLETE THE FOLLOWING

1) Name and WSSN of source water supply system (seller) _____

2) Does the water service contract require water producer/seller to review and approve customer/wholesale/bulk purchaser water system construction plans?
☐YES ☐NO

If yes to #2, the producer/seller approval letter must be attached when submitted to DEQ.

21. **Owner's Certification** The owner of the proposed facilities or the owner's authorized representative shall complete the owner's certification. It is anticipated that the owner will either be a governmental agency (city, village, township, county, etc.) or a private owner (individual, company, association, etc.) of a Type I public water supply.

OWNER'S CERTIFICATION

I, _____ (name), acting as the _____ (title/position) for
(print) (print)

_____ (entity owning proposed facilities) certify that this project has
(print)

been reviewed and approved as detailed by the Plans and Specifications submitted under this application, and is in compliance with the requirements of 1976 PA 399, as amended, and its administrative rules.

_____ _____ _____
Signature* Date Phone

*Original signature only, no photocopies will be accepted.

PROJECT BASIS OF DESIGN – FOR WATER MAIN PROJECTS

PROJECT NAME: _____

For this PROJECT the following information must be provided per Act 399 unless waived by the Department. For projects other than water main installation, or if additional space is needed, attach separate sheet(s) with detailed Basis of Design calculations.

A. A general map of the initial and ultimate service areas
☐Included on engineering plans ☐Attached separately

B. Number of service connections served by this permit application _____

C. Total number of service connections ultimately served by entire project _____

D. Residential Equivalent Units (REUs) served by this permit application _____

E. Total Residential Equivalent Units (REUs) ultimately served by entire project _____

F. Water flow rates for proposed project based on REUs listed in "D' and "E" above

1. Initial design average day flow (mgd) _____
2. Initial design maximum day flow (mgd) _____
3. Total design average day flow (mgd) _____
4. Total design maximum day flow (mgd) _____
5. Required fire flows: (1) _____ gpm for _____ hours

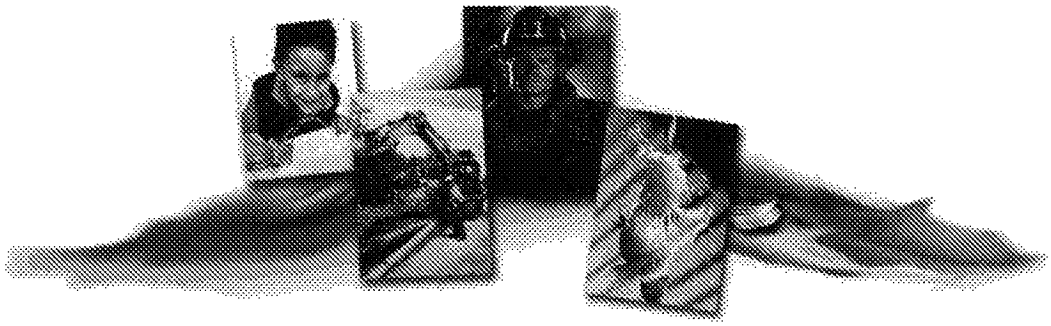
G. Actual flows and pressures of existing system at the connection point(s) (2)

_____ gpm at _____ psi
_____ gpm at _____ psi
_____ gpm at _____ psi
_____ gpm at _____ psi

H. Estimated minimum flows and pressures within the proposed water main system (3) _____ gpm at _____ psi

(1) Every water system must decide what levels of fire fighting flows they wish to provide. Fire flow should be appropriate for the area (residential, commercial, industrial) being served by the project. Typical fire flow rates can be obtained from the water supply, local fire dept., ISO or AWWA. The water system must then be designed to be able to provide the required fire flows while maintaining at least 20 psi in all portions of the distribution system.

(2) Flows and pressures at the connection points must be given to determine if the existing water main(s) are able to deliver water to the new service area. These numbers can be obtained from a properly modeled and calibrated distribution system hydraulic analysis or hydrant flow tests performed in the field. If more than one connection is proposed, list as needed.



(3) List what the estimated minimum flows can be expected in the proposed water mains based on estimated water demands, head losses, elevation changes and other factors that may affect flows, such as dead end mains.

City of Flint Water
Action Steps for Week of November 2-6

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	Meeting held on 10/29/15 to discuss time line
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
3.	Assist After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	Negotiations underway to contract with the Genesee County Health Department
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A summary report for Freeman Elementary School has been drafted
7.	Contact DHHS regarding lead education material for schools; provide information as requested by DHHS	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; action items created
8.	Follow up with city of Flint regarding corrosion control treatment and their plans to address requirements and options provided for in 10/30/15 DEQ letter	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
9.	E-mail city of Flint regarding timing to install corrosion control now that the construction permit has been issued	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	
10.	Review Monthly Operation Reports for Standby Operation of Flint Water Treatment Plant with city of Flint; draft letter to city of Flint documenting Standby Operation requirements	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	
11.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues; check weekly for status update	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Issues regarding soil erosion controls during construction are being addressed
12.	Continue evaluating city of Flint Service Line Record status and comparison to sampling pool	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Cross-referencing process has begun
13.	Provide DHHS with any available cross-reference information regarding lead service lines and plumbing materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
14.	Develop childcare facility guidance or review DHHS-related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; DHHS to provide materials
15.	Develop draft sampling protocol for residential exposure assessment for DHHS	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
16.	Make progress on drafting a generic school sampling guidance document for statewide distribution; target audience: schools served by municipal water	DEQ and LARA	Jim Sygo Steve Busch Richard Benzie	Final draft of school sampling protocol has been written and is awaiting final review
17.	Attend 11/5/15 meeting arranged by DHHS regarding residential elevated blood lead investigations and water testing	DEQ and DHHS	Jim Sygo George Krisztian Steve Busch

Assisting Schools and Child Care Facilities in Addressing Lead in Drinking Water

EXECUTIVE SUMMARY

The American Water Works Association (AWWA) is committed to providing information that helps water suppliers in their role as guardians of public health. Exposure to lead at schools and child care facilities is an issue of growing concern to EPA and some states.

Lead is a significant public health issue. Over the past several decades significant steps were taken to reduce lead from a variety of sources: fuel, paint, air pollution, and plumbing components. Drinking water utilities are also doing their part to reduce lead exposure. Community water systems actively manage and monitor the drinking water they provide to control corrosivity, and thereby reduce the potential to leach lead from household plumbing. Some water systems take additional measures like purchasing low-lead / no-lead distribution system components and others have proactive lead service line replacement programs. Steps also have been taken to identify and reduce lead exposure in schools, but recent events suggest that additional attention may be appropriate in some school and child care facilities.

School and child care administrators are responsible for limiting lead exposure in their facilities, but some water suppliers may be in a position to provide valuable assistance by working with local health departments, schools and child care facilities. We hope you find the information provided in this document helpful as you consider your utility's ability to inform or assist school and child care facilities in the communities you serve.

The following compares and contrasts EPA's guidance to schools and child care facilities under the Lead Contamination Control Act (LCCA) and the Lead and Copper Rule (LCR). It also provides a brief overview of what is entailed in monitoring for lead in schools and child care facilities and the process for undertaking remediation. This report describes a range of assistance utilities can provide to schools and child care facilities based on local needs and resources. Most importantly, it identifies key points of coordination, and provides basic information that the utility can use in communicating about lead in drinking water.

While, this report was prepared with a focus on U.S. regulations, the report premise and suggestions are generally applicable. We hope that this document will be useful to our water supplier members in Canada, Mexico, and other countries.

Assisting Schools and Child Care Facilities in Addressing Lead in Drinking Water

INTRODUCTION

Lead is a significant public health issue, and it is not only a drinking water issue. Other potentially more significant sources of lead include paint and dust. In addition, schools face numerous other environmental challenges. Consequently, EPA and the Department of Education encourage schools to think of building design, maintenance, and remediation holistically (http://cfpub.epa.gov/schools/). While schools and child care administrators bear the responsibility for minimizing lead exposure in their facilities, some water suppliers may be in a position to provide valuable assistance by collaborating with local health departments, schools and child care facilities to help facility administrators better understand how to monitor for and manage lead in drinking water at their facilities.

Overview

The issue of lead in drinking water has returned to the national spotlight after a decade of relative calm. Most water utilities have been very successful in implementing effective corrosion control programs and complying with the requirements of the Lead and Copper Rule (LCR). In spite of this, utilities are facing renewed regulatory, legislative and public scrutiny, attributable largely to the discovery of elevated levels of lead in tap water in a few high-profile communities. Lead exposure in schools is only one aspect of this scrutiny, but it has received considerable attention.

The reduction of lead exposure in schools and child care facilities is the responsibility of the administrators of those facilities. This responsibility includes, but is not limited to, minimizing lead levels in the drinking water system within the facility. Water utilities are not legally responsible for the lead levels in the water systems of schools and child care facilities unless the facility maintains its own supply and is classified by the state as a public water system.

A lead-in-drinking-water problem may be identified by a community's health department, school system, an individual school or child care facility, or the general public. By being prepared for this issue, the utility can better respond to inquiries and, where appropriate, develop more effective collaborations with schools and child care facility managers.

Health Effects

Lead builds up in the body over time and can cause damage to the brain, red blood cells and kidneys. According to the Centers for Disease Control (CDC), of all people, young children face the most danger from exposure to lead because their growing bodies absorb lead more easily than adults' bodies. For children 5 years old and younger, lead levels of 10 micrograms or more in a deciliter of blood can damage a child's ability to learn.

How Lead Can Get Into Drinking Water

A child's greatest exposure to lead is typically from contaminated paint, dirt and dust. However, lead in drinking water can contribute to overall lead exposure. Lead contamination is rarely found in sources of drinking water such as rivers, wells and reservoirs at significant concentrations. It's almost never present in water leaving a treatment plant or traveling through mains. However, lead enters drinking water as a result of corrosion, as water comes into contact with lead pipes, lead service connections, solder and plumbing fixtures.

Community water systems are required under the LCR to control the corrosivity of water. Ninety-six percent of community water systems comply with the LCR.[1]

Lead may be present in school and child care plumbing systems, water coolers, bubblers, and drinking fountains. The amount of lead found in the tap water depends on the plumbing materials present, the pH of the water and other water quality factors.

Recognizing the importance of minimizing lead exposure in schools and child care facilities, the U.S. Congress passed the Lead Contamination Control Act (LCCA) of 1988. The LCCA provided information for repairing or replacing lead-lined water coolers and guidance to schools and child care facilities on methods to test and reduce lead exposure in drinking water.

The LCCA caused many school systems and child care facilities to evaluate lead in water coolers and plumbing during the early 1990s, and the LCCA remains the regulatory vehicle for management of lead in drinking water in these facilities. Compliance with the LCCA on the part of schools is voluntary, in sharp contrast to the mandated provisions of the Lead and Copper Rule (LCR), which applies to public water systems. Differences between the LCCA guidance and the LCR requirements are a source of confusion, and, at times, misinformation in the media and the public. It is essential that utility personnel have a thorough understanding of the differences between the two rules and an awareness of lead in drinking water issues in schools and child care facilities in their communities. Toward that end, this document:

1. Summarizes the provisions of the LCCA guidance and the LCR requirements and highlights the distinguishing differences.

2. Describes the steps school systems and child care facilities may take to effectively manage lead levels in the water supplies in their facilities.

3. Provides drinking water suppliers with information and tools they may use to assist school and child care administrators in addressing lead in drinking water.

[1] Summary of lead action level exceedances for medium (3,300-50,000) and large (>50,000) public water systems, USEPA, http://www.epa.gov/safewater/lcrmr/lead_data.html

REGULATORY REQUIREMENTS
A Comparison of the Lead Contamination Control Act Guidance Manual and Lead and Copper Rule Requirements

Regulatory Background

The Safe Drinking Water Act (SDWA) is the legislation that addresses lead in public drinking water. The LCCA and the LCR work together to minimize lead in drinking water. The goal of the LCR is to minimize lead and copper in drinking water, primarily by reducing water corrosivity. The LCR sets specific requirements for public drinking water systems. This is in sharp contrast to the LCCA, which addresses lead exposure at individual outlets in schools. The LCCA resulted in federal guidance applicable to schools and child care facilities, but it did not set regulatory requirements.

EPA Guidance Under SDWA and LCCA

Failing to meet requirements specified in state and federal regulations results in violations, and their associated fines and penalties. In addition to setting regulatory requirements EPA provides technical information and advice through guidance. EPA guidance is not compulsory, but it is provided with the intent of assisting the recipients to achieve national public health objectives and where there are related regulatory requirements, achieve compliance with those requirements.

EPA is now in the process of updating its guidance documents for public drinking water systems (i.e., LCR guidance), and for schools and child care facilities (i.e., LCCA guidance).

Some states have adopted rules and requirements beyond these national statutes and rules. Consequently, the primacy agency for state rules and, in most instances the local health departments, are the critical points of contact on the issue of lead in schools.

The Lead Contamination Control Act

The LCCA was signed into law in November 1988. This law was intended to reduce exposure to lead from all sources, including lead in school drinking water supplies. The LCCA required:

1. A recall of drinking water coolers with lead-lined tanks;
2. Prohibition of the sale and manufacturing of any drinking water cooler that was not "lead-free"[2];
3. Development of guidance to educational agencies and schools including child care facilities on sampling and testing protocols; and

[2] LCCA defined "lead-free" to mean "not more than 8 percent lead; except that no drinking water cooler which contains any solder, flux, or storage tank interior surface which may come in contact with drinking water shall be considered lead free, if the solder flux, or storage tank interior surface contains more than 0.2 percent lead."

A school is ...

Section 1461 of SDWA defines "school" to mean generally any elementary school or secondary school and any kindergarten or day care facility.

(3) Local educational agency. – The term "local educational agency" means-
(A) any local educational agency as defined in section 198 of the Elementary and Secondary Education Act of 1965 (20 U.S.C. 3381),
(B) the owner of any private, nonprofit elementary or secondary school building, and
(C) the governing authority of any school operating under the defense dependent's education system provided for under the Defense Dependent's Education Act of 1978 (20 U.S.C.921 and following). (SDWA, Section 1461, Definitions)

4. Public notification of the availability of lead testing results.

In 1994, EPA developed a guidance manual entitled "*Lead in Drinking Water in Schools and Nonresidential Buildings*". The Guidance Manual offers: background information about the sources and health effects of lead; descriptions of how lead gets into drinking water; a description of the regulation of lead in drinking water; guidance for developing plumbing profiles and sampling plans, and remedies when elevated lead levels are observed. The Guidance Manual is available on the EPA Office of Ground Water and Drinking Water's website at: www.epa.gov/safewater/Pubs.

"Schools" vs "Child Care Facilities"

Sampling protocols for lead in drinking water at child care facilities are the same as those for schools.

EPA required states to develop water-testing programs for schools. However, in 1996, a federal court determined that such a federal regulatory program couldn't be imposed on states. EPA interpreted this decision as prohibiting the agency from mandating water testing in schools. Consequently, where school and child care facility lead sampling is done, it is voluntary unless it is undertaken to comply with state regulations. In the spring and summer of 2004, EPA compiled information on individual state LCCA activities. This information is available at http://www.epa.gov/safewater/lcmr/.

Sampling Protocol

The LCCA guidance includes a sampling protocol, which **recommends** collection of a 250 milliliter (mL) "morning, first-draw water sample" (e.g., sampling after an 8 to 18-hour stagnation period). In so doing, the LCCA guidance targets the "first draw" water from the sampling point in an attempt to represent worst-case water consumed by students. This contrasts with the LCR sampling protocol, which **requires** collection of a one-liter "first-draw" sample (e.g., sampling after a 6- to 8-hour stagnation period). The LCR samples represent the contribution of internal plumbing to lead levels. The difference in the LCCA guidance and LCR sampling protocols can lead to a great deal of confusion and thereby increase the challenge of accurately describing the resulting data to decision-makers and stakeholders.

Additional Samples If Initial Samples are Elevated

The LCCA guidance recommends that samples be taken after a 30-second flush at those sampling locations with initial lead levels greater than 0.020 mg/L (20 ppb). Most states have adopted the 0.020 mg/L (20 ppb) recommended trigger level

for follow-up actions, while several have opted for 0.015 mg/L (15 ppb) (the LCR Action Level). Consequently, it is important to understand how individual states administer their programs and to maintain an open dialogue with state regulators regarding program implementation.

Public Education

When schools and child care facilities conduct monitoring for lead in drinking water, EPA recommends that they:

1. Make available a copy of the sampling results for "inspection by the public, including teachers, other personnel, and parents."

2. Notify relevant parent, teacher, and employee organizations that sampling program results are available.

Table 1 on page 7 briefly summarizes the provisions of the LCCA guidance; Appendix A provides a more detailed summary.

Remediation

Addressing lead in drinking water may require both short- and long-term solutions. Decisions for one remedy over another will be based on such factors as likelihood of success, availability of water, cost, and staffing requirements.

Some examples of remedies are listed in Appendix I. More detailed explanations, including information about advantages and disadvantages, are in EPA's LCCA guidance.

The Lead and Copper Rule

The LCR, finalized in June 1991 and later amended in January 2000, applies to public water systems. Under the LCR, no more than 10 percent of samples from a public water system may exceed the rule's Action Levels, 0.015 mg/L (15 ppb) for lead and 1.3 mg/L for copper.

When the Action Level is exceeded, specific follow-up steps include corrective action to implement optimized corrosion control and public notification. The LCR provisions apply to water suppliers that serve schools and child care facilities. If an individual school or child care facility supplies or treats its own water supply, it is considered a public water system and must comply with the rule provisions. Additional information about the LCR is available on the EPA Office of Ground Water and Drinking Water's website at: http://www.epa.gov/safewater/lead/index.html

At present the LCR is applicable to community water systems and non-transient non-community water systems. Some schools and child care facilities that have their own water supply are, therefore permitted public water systems. In these instances, the facility is also subject to the applicable provisions of the LCR.

The LCCA guidance targets material remediation

Types of Public Water Systems

Community Water System (CWS): A public water system (PWS) that supplies water to at least 15 service connections used by year-round residents or regularly serves at least 25 year-round residents.

Non-Transient Non-Community Water System (NTNCWS): A PWS that regularly supplies water to at least 25 of the same people at least six months per year, but not year-round. Some examples are schools, factories, office buildings, and hospitals that have their own water systems.

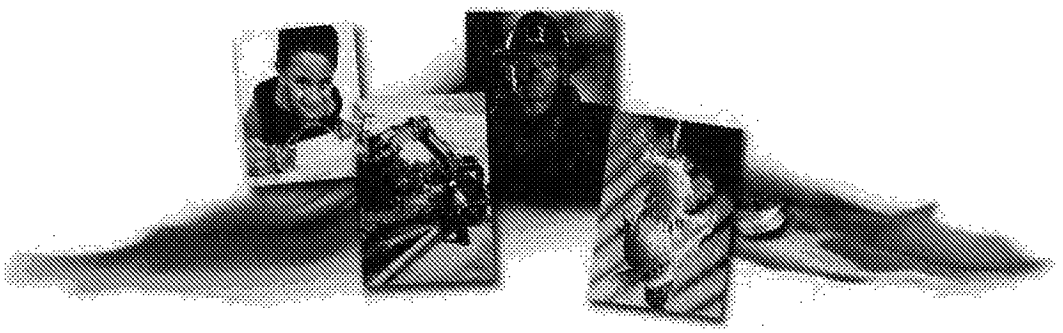
Transient Non-Community Water System (TNCWS): A PWS that does not regularly serve at least 25 of the same persons over six months per year. Examples are places such as a gas station or campground where people do not remain for long periods of time

while the LCR is focused on reducing the corrosivity of delivered water. These two control strategies complement one another, but their differing approaches may also complicate public education efforts. Table 1 summarizes other distinguishing features of the LCCA guidance and LCR requirements for lead management.

The Lead Ban

Amendments to the Safe Drinking Water Act (SDWA) banned the use of lead pipes, solder, and flux effective June 1986 in drinking water plumbing. Therefore, any plumber, general contractor, etc. who used lead solder, pipe or flux after that date is in violation of federal law.

Prior to the 1996 amendments, the SDWA required faucets and other plumbing fixtures to contain no more than 8 percent lead. The 1996 amendments to the Safe Drinking Water Act (SDWA) required EPA to establish a performance standard to govern the leaching of lead from endpoint devices intended to dispense water for human consumption. The EPA selected Section 9 of *ANSI/NSF Standard 61: Drinking Water System Components-Health Effects* as this performance standard. After August 6, 1998, it was unlawful for any pipe or plumbing fitting or fixture that is not "lead free" to be introduced into commerce.



Plumbing Materials

Plumbing materials purchased for use in schools and child care facilities should comply with the lead ban, and meet ANSI / NSF standards or more stringent lead content requirements.

Prior to the 1996 amendments, the Safe Drinking Water Act required faucets and other plumbing fixtures to contain no more than 8 percent lead. The 1996 amendments retained the 8 percent lead content requirement and further mandated that faucets, drinking fountains and other drinking water dispensing devices meet the performance-based lead leaching requirements of ANSI/NSF Standard 61, Section 9.

Table 1. Summary of Distinguishing Features of the Lead Contamination Control Act Guidance and the Lead and Copper Rule Requirements

Feature	Lead Contamination Control Act Guidance	Lead and Copper Rule Requirements
Sampling Sites	Each cold water tap in a facility	Cold water taps in high risk homes/buildings
"First Draw" Sample Size	250 mL	1000 mL
Stagnation Period	Morning, first-draw water sample" (e.g., sampling after an 8 to 18-hour stagnation)	"First-draw" sample (e.g., sampling after a 6- to 8-hour stagnation period)
Action Level	0.020 mg/L at each cold water tap	0.015 mg/L in 90% of taps
Action(s), if Lead Limit Exceeded	Additional samples recommended; suggests remedial measures	Mandatory corrective actions such as public education, lead service line replacement, increased monitoring and corrosion control treatment
Sampling Schedule	None specified	Initially, two 6-month monitoring periods; Reduced monitoring – June through September each year or once per three years
Certified Laboratory Requirement	Yes	Yes
Public Notification Requirements	Make results available in the administrative offices of the local educational agency; must notify parents, teachers, and employee organizations of the availability of results	Must present data in annual Consumer Confidence Report. Full notification required only if Action Level is exceeded.

LEAD IN SCHOOLS AND THE WATER SUPPLIER

Under the LCCA guidance, school and child care administrators are responsible for taking steps to minimize exposure to lead in drinking water at their facilities. These facilities can obtain technical assistance from local health departments, but as the local water supplier, you may be in a position to provide information that facilitates appropriate action in the communities you serve.

Getting Prepared

To communicate effectively with health departments, school, and child care administrators about lead in drinking water, you may choose to first provide a clear presentation of your utility's actions related to this issue. If you effectively demonstrate the steps taken to reduce lead at the tap in the community water supply, you affirm your utility's commitment to public health. You also provide the technical information necessary for future discussions on lead in school drinking water.

Compiling and reviewing the following information is a worthwhile investment of time:

1. Review your utility's LCR compliance status.
    - Do you have a description of your program to maintain optimized corrosion control (OCC)?
    - What are your monitoring requirements and what is your compliance record with the LCR Action Level?
    - When is compliance monitoring occurring?
    - Do you have a summary of pertinent data in an easily-understood format that can be provided to the school or child care facility staff?
2. Review or develop your utility's service line and meter data for discussions with school and child care administrators.
    - Are there lead service lines or compound meters with lead components leading to school or child care facilities?

Determine how the LCCA is administered in your state and locally. In most communities, the local health department is the key agency in identifying and prioritizing risks to public health. It is also the oversight agency most likely to provide direction to schools on lead issues. Opening a discussion with the local health department provides an opportunity to exchange information and identify shared priorities. Key questions include:

1. What is the status of state regulations arising from the LCCA?
2. What actions have been taken to-date?
    - What notifications, requests, or guidance has been distributed to

schools and/or child care facilities?

- What actions are already underway by local school board, town, city or county governing bodies, or the facility administrators?

Communication

When compatible with public health agency activities, utilities may choose to communicate directly about lead in drinking water with schools and child care facilities in communities they serve.

> **Agency Perspective**
>
> Some states are already actively encouraging community water systems to interact with schools and child care facilities. These efforts reflect a national effort by U.S. EPA to promote such local dialogues.

It is important to keep your utility's governing body informed about the issue of lead in drinking water, your utility's compliance record with the LCR, and your state's response to the issue of lead in school and child care drinking water. Also, before assistance is offered, carefully identify the costs and benefits of such assistance and be assured of the governing body's policy and financial support.

In order to help them answer questions from the general public, utility personnel should also be informed about health risks associated with lead in drinking water and your utility's compliance record. Your utility's compliance status should be communicated to customers through your Consumer Confidence Report and other available means (i.e., website, newsletters, etc.).

> **Consumer Confidence Report**
>
> The CCR provides an opportunity to communicate your utility's compliance status to customers.

Planning

Communication efforts on lead in school drinking water require thoughtful planning. The following questions may be helpful in structuring your approach:

1. What is the potential scope of the issue? Is there likely to be a widespread problem with lead in drinking water based on your current water quality, LCR history, status of LCCA activities, the number and age of facilities or other factors?
2. What is the likelihood that your customers understand the issues associated with lead in drinking water?
3. What personnel and informational resources will be needed to assist schools and child care administrators?

Reaching Out

When engaging health departments, schools (public, private, or parochial), and child care facilities on the topic of lead in water, water suppliers should keep in mind that many school systems took action more than a decade ago when the LCCA was first signed into law. If the school or child care facility or system integrated appropriate practices into its operation and maintenance programs, it is less likely to face significant lead challenges.

If a utility decides to reach out to health departments, schools, or child care facilities on the issue of lead in drinking water, a simple phone conversation may be enough to initiate the appropriate action steps. However, a brief letter may be more effective.

Initial letters sent to these facilities and agencies should clearly state the issue at hand and serve to open a dialogue on this issue. A sample letter is provided in Appendix B.

Correspondence with the highest level of authority at the school or child care facility or system usually encourages the widest distribution within the organization. In situations where it is not clear who are the most appropriate recipients, contact

the school or school system. Correspondence is typically most effective if combined with follow-up contact.

Identifying all of the child care facilities in a community can be quite challenging. Appendix C provides several resources that are available to find these facilities.

Identifying Child Care Facilities

State licensing and registration programs for child care providers are the most centralized sources of information on child care facilities.

Examples of Possible Utility Assistance

Utilities have a wide range of expertise and resources available to assist schools and child care facilities in their responsibility to minimize exposure to lead in drinking water. While your utility must decide what level of assistance is appropriate, you may consider a range of opportunities for collaboration. Table 2 on page 12 illustrates a range of possible interactions with schools, child care facilities, and local health departments, but it is by no means all encompassing. Innovative utilities, schools, and local health departments will undoubtedly identify additional ways to work together.

Health Department

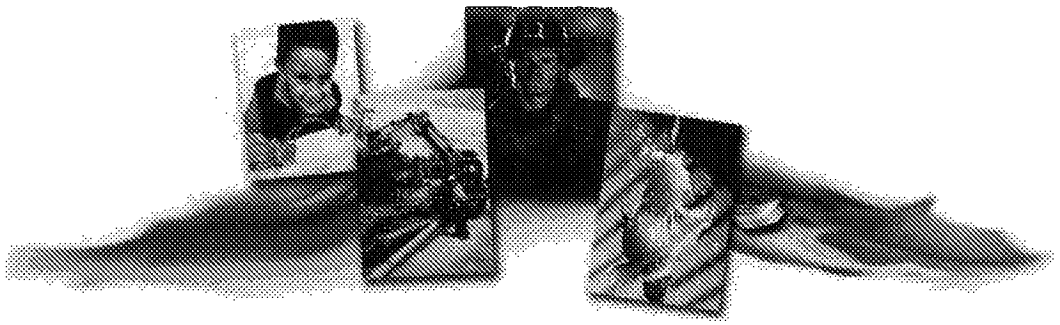
Health departments are responsible for balancing risk and costs of reducing risks in their community and may determine that current actions are appropriate. A utility's first contact should be through the Health Department before contacting schools and any future actions should be guided by the Health Department.

Due to the complexity of lead in drinking water issues and the number of facilities that may be involved, utilities may incur significant costs in assisting schools and child care facilities. Before offering assistance, utilities should ensure that their governing boards concur with such commitments.

Table 2: Opportunities for Collaboration

Help the School / Child Care Understand the Source of Lead in Drinking Water
A school or child care facility administrator may benefit from a better understanding of how lead leaches from facility plumbing. As a utility, you may choose to provide information on water quality factors affecting the water's corrosivity. You may also explain your corrosion control program to affirm your utility's commitment to minimizing lead exposure at the tap. Simply providing your Consumer Confidence Report (CCR) may be helpful.

Developing a Sampling Plan
Water quality sampling is a familiar task for drinking water suppliers, but not for most schools and child care facilities. Some utilities have informed appropriate school staff about the critical elements of a sound sampling plan. Those elements include identifying and tracking sample locations, proper timing of sample events, sampling protocols and management of sample results.



Proper Sample Collection
Proper sampling technique is essential to obtaining correct lead sample results. Some utilities have assisted school systems and child care facilities in proper sampling protocols. This assistance may include direct participation in training events or a train-the-trainer technical assistance strategy.

Laboratory Services
Water suppliers may provide information on lab services needed for processing lead samples. Assistance in this area has taken a number of forms, including explaining the appropriate analytical methods, identifying certified laboratories and assisting in selection of laboratory services. In some cases, utilities have provided analytical services through their in-house laboratories.

Reviewing Results and Options to Control Lead Exposure
As a water supplier, you may have personnel available to interpret sample results and identify cost-effective control solutions. Utility staff is trained in the basic issues of corrosion chemistry and hydraulics. They also have practical experience operating water distribution facilities, flushing pipe networks, installing automated valves, and employing other procedures unfamiliar to most school and child care personnel.

Utility Assistance in a Targeted Evaluation Effort
In school districts with multiple buildings dedicated to teaching, the water utility may offer support in evaluating lead levels in a limited or targeted group of facilities. For example, the utility might help a school system develop a pilot approach to evaluating its facilities. If successful, the school staff would then apply that approach to other facilities. The utility may also assist in identifying the characteristics of buildings that make them especially vulnerable to elevated levels of lead in the drinking water.

Large-Scale Involvement in Lead Action Plan
Depending on local circumstances (especially governance), a water utility may choose to become deeply involved in addressing school system or child care facility lead action plans. For example, the utility may be an active participant in a stakeholder-based school decision-making process that also includes the local health department.

MANAGING LEAD LEVELS AT THE TAP IN SCHOOLS AND CHILD CARE FACILITIES

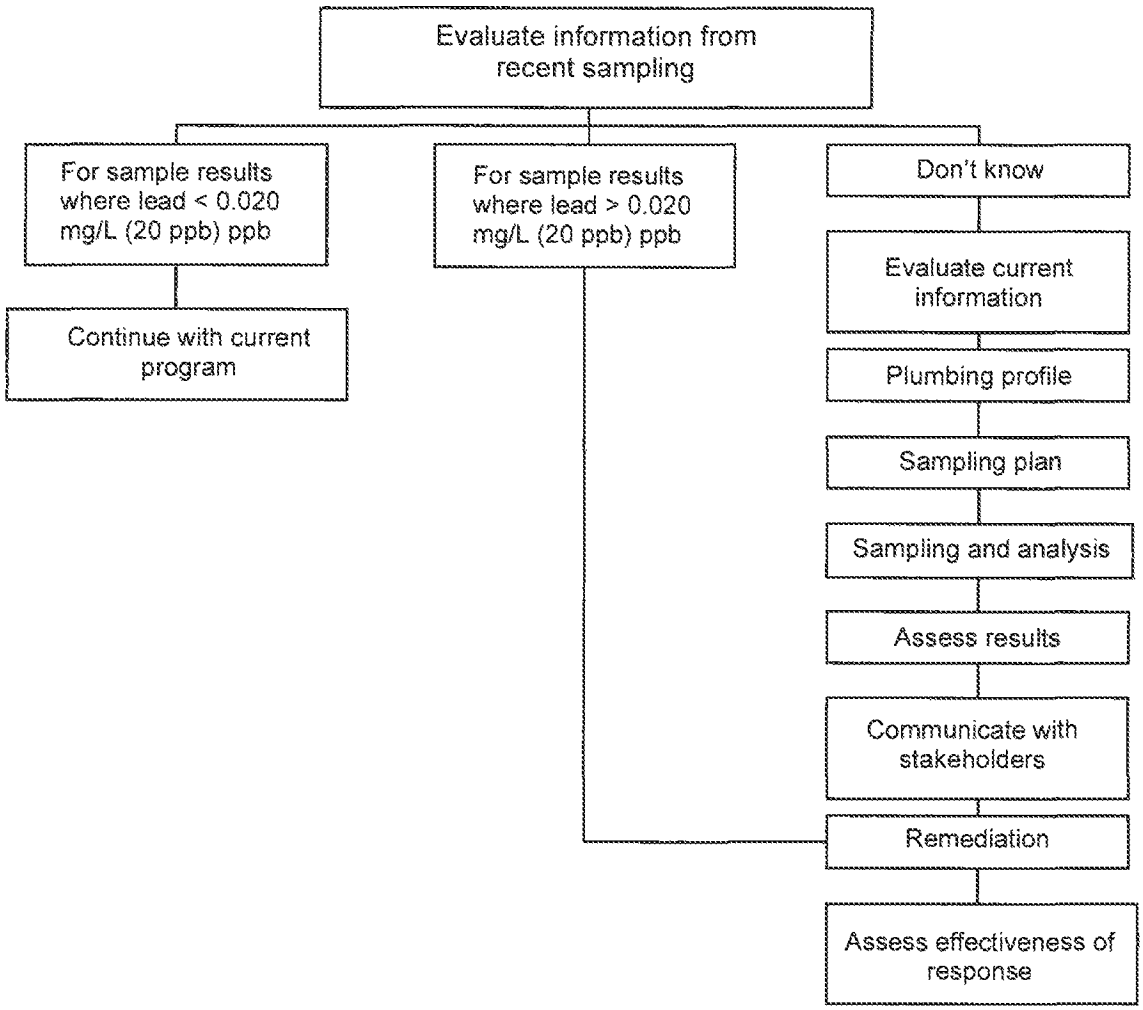
School and child care facility administrators face a large portfolio of environmental and public health concerns. Consequently, some schools employ comprehensive programs to assure compliance with environmental and public health standards. Lead paint, dust abatement, and other lead exposure reduction measures may already be ongoing through a lead poisoning prevention program. Where possible, lead in drinking water should be managed in the context of a multi-media program. Whether such a program exists or not, steps can be taken to assess lead levels in water at drinking water fountains, bubblers, and other outlets.

School systems and child care facilities that already have taken steps to control lead in their facilities and maintain a regular monitoring program are much better positioned to manage lead in drinking water than those confronting the issue for the first time. Addressing lead in drinking water, when elevated levels are identified within a facility, typically involves an initial investment in physical changes to a facility, the introduction of new maintenance practices, and the establishment of an ongoing monitoring program for lead levels.

A facility with an ongoing lead poisoning prevention program that addresses tap water may need little interaction with its water supplier beyond routine communications. However, a facility in which management of lead exposure has not consistently focused on water may need to initiate an Action Plan and consequently may have a greater interest in interacting with the drinking water utility.

Action Plans are typically initiated in a phased manner, during which the school or child care facility:

1. Reviews previous efforts to remove leaded materials, implement lead control strategies, etc.
2. Conducts targeted monitoring (if recent monitoring data are not available) to determine if lead levels appear to be elevated.
3. Develops a detailed Action Plan based upon available information.



An Action Plan to address lead in drinking water must address both technical and communication concerns. Appendix D is an overview of the basic components of such a plan. This overview is supplemented with materials in the appendices (E – K) that water suppliers may provide to school and child care facility managers to inform and assist them in developing their Action Plans.

The components of the Action Plan should be structured to yield an assessment of the situation, a determination of the need for remedial action, development of a remediation strategy, execution of the remediation strategy, and finally, assessment of remediation strategy's effectiveness. More specifically, the plan should incorporate the following elements:

- Plumbing Profile
- Sampling Plan
- Interpretation of Analytical Results
- Action in Response to Findings
- Follow-up Sampling
- Communication

A process for school and child care facility administrators to undertake to evaluate lead levels in drinking water within their facilities is well described in EPA guidance *Lead in Drinking Water in School and Nonresidential Buildings* and *Sampling for Lead in Drinking Water in Nursery Schools and Day Care Facilities* and is summarized in Figure 1.

Figure 1
Managing Lead Levels in the Water Supply of Schools & Child Care Facilities

SUMMARY

Consumers and the media do not always understand how lead enters drinking water, and they are often confused about the water supplier's role in reducing exposure at the tap. However, since lead in drinking water is a water quality issue, the water supplier will often be sought out as the most knowledgeable voice in the ongoing public discussion. Utilities are providing their communities an important service when they proactively communicate potential risks, help the community understand relevant issues, and provide available assistance to school and child care administrators. In providing this service utilities help to ensure that well-reasoned measures are taken to protect public health.

APPENDIX A. RULES AND GUIDANCE ON LEAD IN DRINKING WATER

Lead Contamination Control Act

- This Act resulted in a recall of drinking water coolers with lead-lined tanks and a prohibition on the sale and manufacturing of any drinking water cooler that was not lead-free.
- Defines a "lead free water cooler" as "a drinking water cooler, that each part or component of the cooler which may come in contact with drinking water contains not more than 8 percent lead, except that no drinking water cooler which contains any solder, flux, or storage tank interior surface may contain more than 0.2 percent lead."
- Provides guidance to educational agencies and schools on sampling and testing protocols.
- Sets minimum requirements for notifying the public about lead observations in schools and childcare facilities.
- Requires water samples to be analyzed by a laboratory approved by the state.
- Additional information regarding Lead Contamination Control Act implementation is available through the Internet (http://www.epa.gov/safewater/lcrmr/pdfs/report_lcmr_schoolssummary.pdf)

Lead and Copper Rule

- This regulation applies to waters systems, including schools and child care facilities that provide their own water supplies.
- The Lead and Copper Rule provides a framework for utilities to a) determine if their corrosion control program is effective at limiting lead exposure; b) take additional steps to protect public health; c) and ensure consumers are notified if the utility finds lead above the Action Level in the community.
- The Lead and Copper Rule is based on a "treatment technique" requirement in which the lead Action Level is a trigger -- the Action Level is not health based.
- Monitoring under the LCR takes place at worst-case sampling locations. Samples are taken from water standing overnight in homes where lead pipe or lead solder is present.
- If more than 10% of tap water samples taken in LCR monitoring exceed the action level of 0.015 mg/L (15 ppb) water systems must take additional steps to reduce corrosivity (i.e., improve corrosion control, lead service line replacement).
- If more than 10% of tap water samples taken in LCR monitoring exceed the action level of 0.015 mg/L (15 ppb) water systems must notify area residents via newspapers, radio, TV and other means.
- Additional information regarding the Lead and Copper Rule is available through the Internet (http://www.epa.gov/safewater/lcrmr/lead_data.html)

Summary of Key Elements of the Lead Contamination Control Act

Organization	Responsibility
States and Local Governments	Provide for the dissemination of EPA's guidance document and testing protocol and the list of water coolers that are not lead-free Establish a program to assist local educational agencies in testing for and remedying lead contamination in drinking water from coolers and other sources of lead contamination at schools Make available lead testing results in the administrative offices of the local educational agency for inspection by the public, including teachers, other school personnel and parents Notify parents, teachers and employee organizations of the availability of lead testing results Repair, replace, permanently remove, or render inoperable water coolers that are not lead-free and that are located in schools, unless the coolers are tested and found to not contribute lead to drinking water
Environmental Protection Agency (EPA)	Publish a list of each brand and model of water cooler that is not lead-free, including a list of the brand and model of water coolers with a lead-lined tank and distribute the list to States Publish a guidance document and testing protocol to assist schools in determining the source and degree of lead contamination in school drinking water supplies and in remedying the contamination.
EPA and State Primacy Agencies	Publish and make available to the public, upon request, a list of laboratories certified by EPA or the State, to conduct analyses of lead in drinking water
Consumer Product Safety Commission	Issue an order requiring manufacturers and importers of water coolers with lead-lined tanks to repair, replace, or recall and provide a refund for such coolers
Water cooler manufacturers, importers, others	Do not sell any drinking water cooler, listed by EPA or any cooler that is not lead free*, including a lead-lined cooler.

* A lead free water cooler is defined as "a drinking water cooler, that each part or component of the cooler which may come in contact with drinking water contains not more than 8 percent lead, except that no drinking water cooler which contains any solder, flux, or storage tank interior surface may contain more than 0.2 percent lead."

Cooler Information

The LCCA, an amendment to the Safe Drinking Water Act, was signed into law on October 31, 1988. The potential for water supply coolers to supply lead to drinking water in schools and day care facilities was a principal focus of the legislation. The LCCA mandated the Consumer Product Safety Commission (CPSC) to order the repair, replacement or recall and refund of drinking water coolers with lead-lined water tanks. In addition, the LCCA called for a ban on the manufacture or sale in interstate commerce of drinking water coolers that are not lead-free. Civil and criminal penalties were established for violations of this ban. A consent agreement calls on cooler manufacturer Halsey-Taylor to provide a replacement or refund program that addresses all the coolers listed as well as "all tank-type models of drinking water coolers manufactured by Halsey-Taylor". Halsey-Taylor agreed to notify the public of replacement and refund program for all tank type models. Contact: Halsey-Taylor, 2222 Camden Court, Oak Brook, IL 60523, (630) 574-3503.

Water Coolers With Other Lead Components

EBCO Manufacturing

All pressure bubbler water coolers with shipping dates from 1962 through 1977 have a bubbler valve containing lead. The units contain a single, 50-50 tin-lead solder joint on the bubbler valve. Model numbers for the coolers in this category are not available.

The following models of pressure bubbler coolers produced from 1978 through 1981 contain one 50-50 tin-lead solder joint each:

CP3	DP15W	DPM8	7P	13P	DPM8H	DP15M	DP3R
DP8A	DP16M	DP5S	C10E	PX-10	DP7S	DP13SM	DP7M
CP5	WTC10	CP5M	CP10	13PL	DP7MH	DP7WD	DP13M-60
EP5F	DP5F	DP14M	DP20	SP12N	CP10-50	DP15MW	DP3R
DP14S	DP5M	EP10F	DP13A	DP13M	DP20-50	DP13A-50	DP14A-0/60
DP10F	CP3H	DP13S	CP3-50	DP7SM	DP8AH	DP10X	DP3RH
CP3M	DP7WM						

Halsey-Taylor

Lead solder was used in these models of water coolers manufactured between 1978 and the last week of 1987:

WMA-1	SCWT/SCWT-A	SWA-1	DC/DHC-1
S3/5/10D	BFC-4F/7F/4FS/7FS	S300/500/100D	

The following coolers manufactured for Haws Drinking Faucet Company (Haws) by Halsey-Taylor from November 1984 through December 18, 1987, are not lead-free because they contain 2 tin-lead solder joints. The model numbers:

HC8WT	HC14F	HC6W	HWC7D	HC8WTH
HC14FH	HC8W	HC2F	HC14WT	HC14FL
HC14W	HC2FH	HC14WTH	HC8FL	HC4F
HC5F	HC14WL	HCBF7D	HC4FH	HC10F
HC16WT	HCBF7HO	HC8FH	HC4W	HC8FH
HC4W	HWC7			

Halsey-Taylor Water Coolers with Lead-Lined Tanks

The following six models have one or more units in the model series with lead-lined tanks:

WM8A	WT8A	GC10ACR	GC10A	CG5A	RWM13A

The following models and serial numbers contain lead-lined tanks:

WM14A Serial No. 843034	WM14A Serial No. 843006
WT11a Serial No. 222650	WT21A Serial No. 64309550
WT21A Serial No. 64309542	LL14A Serial No. 64346908

APPENDIX B. SAMPLE UTILITY LETTER TO SCHOOLS AND CHILD CARE FACILITIES

[Date]

[Superintendent of Schools]
[Address]

Dear [Superintendent]:

Exposure to lead poses a serious health risk to children, particularly those 5 years of age and younger. While the majority of children's lead exposure comes from sources such as soil contamination, dust, or paint chips, lead in drinking water can be a contributing factor to overall lead exposure.

Lead is not a common contaminant in drinking water when it is distributed from the water treatment plant to customers. However, lead may enter water after coming into prolonged contact with a building's pipes and plumbing fixtures.]

As you may know, there are 3 major regulations that speak to minimizing lead in drinking water.

- The Lead and Copper Rule requires water utilities to control the corrosivity of its water.
- The Lead Contaminant Control Act (LCCA) addresses lead-free components in water coolers and provides guidance for schools and child care centers on sampling, analytical protocols, and public availability of the information.
- The Safe Drinking Water Act addresses the maximum lead content and leaching potential of plumbing material and fixtures.

We have included a summary of the results from our Lead and Copper Rule sampling over the past few years. Similar information is included in our annual Consumer Confidence Report mailed to all residences in the May/June timeframe each year.

We have attached the EPA brochure "Is there Lead in the Drinking Water?" which is part of the agency's Lead-Free Drinking Water in Schools Program. It gives an overview of the issue with website links and phone numbers for additional information.

We hope you find this information helpful. If you would like to discuss this further, or have any questions, please call [Name of water utility representative] at [Water utility representative's telephone number].

Sincerely,

[Water Utility Manager]

cc: [Local public health officials]

Enclosures

APPENDIX C. IDENTIFICATION OF SCHOOLS AND CHILD CARE FACILITIES

Listed below are resources that can assist utilities in identifying the schools and child care facilities within their service area.

- The Local Board of Education
- The state licensing office – a particularly useful resource in identifying child care facilities
- Child care information services as provided by the local government
- Child welfare advocacy groups
- The local health department
- Fire and police departments
- The water utility's billing system database
- The water utility's cross-connection control database
- The local telephone book/yellow pages (and equivalent web-based phone books)

APPENDIX D. SUMMARY OF STEPS IN A FACILITY ACTION PLAN

Develop a Plumbing Profile

A plumbing profile can help to determine if lead is likely to be a problem in the facility. It will also assist in prioritizing the sampling locations that are believed to pose the greatest risk. In the context of developing a plumbing profile, school and child care administrators should ensure that water coolers recalled under the LCCA are repaired or removed. In addition, they should understand the community's water and know what steps are already being taken to reduce the potential for lead to enter drinking water. A sample plumbing profile is provided in Appendix E.

Plumbing Profile

By identifying what materials are used in facility plumbing, it is possible to determine if monitoring is needed and if so where it would be most effective.

Develop a Sampling Plan and Sampling Protocol

A sampling plan is essential to obtaining high-quality data that characterize the levels of lead found in the school or child care facility's water supply. These data will form the basis on which to make remediation decisions. It is important for all involved to emphasize that the success of the Action Plan hinges upon a good sampling plan. The sampling plan should incorporate the following components:

Systematic identification and labeling of sampling points in the facility does not have to be elaborate, but it is essential to a sampling program.

- A prioritized list of sampling points to be included in the sampling effort, drawing on the results of the plumbing profile. Of highest priority should be those faucets/taps where water is either consumed or used for food preparation.
- A **written** sampling protocol that answers the following questions:
  - What should be the volume of the "first-draw" samples? The EPA Guidance Manual recommends a 250 mL sample.
  - How long is the period of stagnation prior to sample collection? In most instances, this ranges from 8 to 18 hours, with absolutely no water use during that period if possible.
  - How will location codes be assigned to each sampling point? Each sampling point should be labeled with a location code.
  - Which certified laboratory will perform the lead analysis?
  - How will samples be shipped to the laboratory?
  - What detailed record keeping form will be used? The form should include at a minimum: type of sample (i.e., first flush); date of sample collection; time of sample collection; name of sampler; sample location code; the manufacturer of the tap / outlet (bubbler, cooler, faucet, etc.); the model number of the tap / outlet; the name of the building from which the sample was collected. An example recordkeeping form is provided in Appendix H.

Data Management

For an assessment of monitoring results to be meaningful, a sound data management system must be established in the Action Plan and followed diligently during monitoring and reporting. Data management should be appropriate to the scale of the monitoring effort (i.e., managing data for a single structure need not be as elaborate as a data system for an entire school system). If lead contamination is found, sample records and test results will assist in pinpointing the sources of the problem and indicate possible remediation measures.

Assessing the Results

The analytical results should be evaluated with an established benchmark level[3] or point of reference. The LCCA guidance suggests 0.020 mg/L, but some states have chosen other levels. Sampling points with lead levels that exceed the benchmark should be considered candidate sites for either re-sampling (in order to confirm the results), removal from service, or remediation.

Action in Response to Findings - Develop a Solution

The analytical results may reveal situations that require further investigation. For example, if a child care facility exhibits elevated levels of lead, a thorough investigation of plumbing materials in that facility may be warranted. Preparation for investigative efforts should be planned in advance of the initial sampling program, so that a thorough investigation can be completed in a timely manner. Preparations should include but need not be limited to:

1. Identifying how investigation efforts will be prioritized and resources allocated.
2. Preparing staff or contractors to evaluate coolers, fixtures and other factors that might contribute to lead levels at a sampling location.
3. Identifying staff and setting protocols for running water through the outlet and re-sampling.
4. Preparing communication materials to convey results and education materials to parents, students, and staff.
5. Determining what alternative sources of drinking water to provide until remediation is complete.

Lead in drinking water can be a complex problem, and there is no single approach that is suitable for addressing all situations, rather solutions are very site-specific. Decisions will need to be based on the age and condition of a facility's plumbing, the nature of the water supply, testing results and sources of lead contamination. A common immediate action is to immediately remove from service any tap / outlet where elevated lead levels are observed until appropriate remediation measures are identified and instituted. When a tap / outlet is taken out of service, appropriate signage should be displayed until it is remediated.

When lead risks are identified, facility managers must find short- and long-term solutions. Short-term control measures may include:

- Cleaning debris from faucet screens,
- Measures to reduce galvanic corrosion (e.g., dielectric unions, paint or polymer coatings, etc.)
- Maintenance programs to assure adequate turnover of water in the facility's pipes,
- Removing outlets from use, and
- Providing bottled water.

More permanent fixes may include:

- Replacing taps, bubblers, coolers, faucets, or other outlets,
- Correcting improper grounding of electric wiring,
- Installing point-of-use devices,
- Installing corrosion control devices, and

[3] Like the LCR the LCCA guidance refers to this benchmark level as an "action level."

- Removing lead service lines.

Appendix I contains a detailed list of potential control measures and remedies that water suppliers may want to discuss with school and child care administrators.

Follow-Up Samples and Follow-Through

Upon undertaking steps to control lead levels in schools and child care facilities, it is important to test for lead levels to make sure that remediation has been effective. Follow-up sampling should be appropriately timed to allow for passivation to occur. Sampling conducted immediately following remedial measures may result in unrepresentative lead levels.

As noted previously, ongoing monitoring over time is important to ensure that control measures remain effective and that facility operators retain focus on managing lead levels. Maintaining an ongoing awareness of lead in water within the facility management program can facilitate continued reduction of lead levels over time and avoid the recurrence of conditions that might contribute to elevated lead levels. Appendix J includes a maintenance log sheet that can be used for ongoing management of lead in facility plumbing. Also, periodic re-sampling for lead levels in facilities on at least a screening study basis is appropriate to maintain control of lead management.

Communicating on Lead in Schools and Child Care Facilities

Because school and child care administrators are responsible for limiting lead exposure at the tap, they are typically the appropriate entities to communicate on lead in drinking water at their facilities. However, water suppliers are likely to have a role as well. In many cases, parents and the media will look to the drinking water supplier for information about:

- How lead gets into the drinking water supply at the tap,
- What steps are being taken by the water supplier to control lead in drinking water, and
- What consumers can do to reduce their own and their children's lead intake.

Water utilities that make this information available before a problem exists are likely to have more credibility in the eyes of the public in the event of a lead contamination event. Web-based fact sheets, consumer confidence reports, media backgrounders and brochures provide consumers with valuable information to protect their health. They are also valuable tools in a water supplier's overall risk communications strategy. AWWA also has materials available to utilities for this purpose (see Appendix L for example materials). Developing a collaborative communications program on lead in schools with the local health department, schools and child care facility administrators can be of assistance to all parties.

Water suppliers can provide significant support to school and child care administrators as they communicate with consumers through public meetings or with media through news conferences or briefings. Communications are more likely to be clear and consistent when they come from a unified source.

Important Elements in a Communications Strategy

Lead in drinking water can be an emotionally charged issue. An effective communications strategy is critical to explain potential risks, describe technical solutions and build trust among parents, school and child care officials, local health department officials, and water suppliers. Utilities that choose a cooperative, hands-on approach to public communications are better positioned to effectively communicate on this issue with their communities.

Public health agencies and drinking water suppliers can provide information that builds a technical foundation for school communications. For example, state and local public health agencies are responsible for ensuring compliance with the LCR and assisting facility managers in

implementing the LCCA and associated guidance. The local or state health agency possesses expertise and credibility in the area of risk management. Water suppliers deliver non-corrosive water to control lead leaching and have a detailed understanding of delivered water quality. Regardless of the level of participation by the water supplier, a communications strategy on lead in school drinking water should incorporate:

- Defined goals or objectives for the communications efforts.
- Identification of primary and secondary target audiences, including school management, staff, parents and wider school community; local policy makers; advocacy organizations, and media.
- Risk communication to concerned stakeholders.
- Clearly defined messages to be repeated in communications.
- Identification of available communications tools, including, but not limited to, web sites, school newsletters, letters to parents, public meetings, press releases and news conferences.
- Identification of potential language barriers.
- A timeline for key public communications moments, including just before a sampling program begins, after results of testing are obtained, and when solutions are made public.
- Information to media that defines relevant issues and communicates the control strategy.

Engaging Partners in the Action Plan

Water suppliers are one in a wide range of partners who may be available to assist school and child care administrators in their lead control strategies. Local health departments and state primacy agencies are key partners both for the water supplier and school and child care facilities. Whether lead in schools is addressed in a proactive or a reactive mode, most successful case studies suggest that the school or child care leadership benefit from expert third-party voices. The level of involvement among these partners varies, but they may include:

- Local building and plumbing inspection staff
- Teachers organizations
- Parental organizations
- Active community organizations
- Local government (i.e., city, county, town)

In some situations, school and child care facilities may benefit from consultant support. Examples might include assistance from laboratory services, engineering firms and communication experts.

In some school or child care settings the facility administrator may organize a stakeholder committee process. In some instances, the local drinking water utility will participate as a technical resource. The choice and scale of such an effort will reflect the local situation and the size of the school.

APPENDIX E. SAMPLE FACILITY PLUMBING PROFILE

When a detailed facility plumbing profile is needed, answering the following questions can provide useful insights into whether lead is present in a facility's plumbing, and if so, in what portions of the plumbing.

- When was the facility built?
- Have new buildings or additions been added? If so, when were they added? If built since 1986, was lead-free plumbing and solder used?
- When were the most recent plumbing repairs made and where were they located?
- From what material is the service line made?
- From what materials are the facility's potable water pipes made and what is their location? What materials were used to solder the potable water pipes in the system?
- Are brass fittings, faucets or valves used in the facility? Note locations.
- How many bubblers, icemakers, water coolers and kitchen taps are located in the facility? Where are they located?
- What brands and models of water coolers are in the facility? Where is their location?
- Do the faucets have accessible screens, and have they been cleaned?
- Can any signs of corrosion, such as leaks, rust-colored water or stains be detected?
- Is any electrical equipment grounded to water pipes?
- What do the records of previous water testing show?

It may be advisable to consult with a local plumbing expert as you answer these questions.

APPENDIX F. UNDERSTANDING THE SIGNIFICANCE OF PLUMBING PROFILE

When was the facility constructed? Plumbing before 1930 is most likely to contain lead. Between 1920 and 1950, galvanized pipes were used for plumbing. After 1930, copper generally replaced lead. Up until the late 1980s, lead solders were typically used to join copper pipes. The lead-free requirements of the 1986 Safe Drinking Water Act banned lead solder with more than 0.2% lead and plumbing with more than 8% lead. Buildings did not have to be built with certified "lead-free" fixtures until 1997.

Are there new buildings and additions? New buildings are unlikely to have lead pipes, but they are likely to have copper pipes with solder joints. Buildings built prior to 1986 are likely to have joints made of lead solder. Some brass fittings, although they contain less than 8% lead in alloy, may still contribute a significant amount of lead to drinking water.

When were plumbing repairs made? Corrosion is a result of the chemical reaction between water and pipes. Known as galvanic reaction, this can be vigorous in new piping until a protective layer is built up. After about five years, the reaction usually slows down, and lead enters the water as a result of more typical corrosion. If water supplied to a facility is corrosive, lead can remain a problem regardless of the age of the plumbing.

What material is used in the service line? Historically lead piping was used in some communities for service lines that join buildings to public water supplies. Lead pipes are dull gray in color and may be easily scratched by a metal object. Lead pipes can be a major source of lead contamination. Galvanized pipes are gray and usually fitted together with threaded joints. Copper pipes are red-brown in color. Corroded portions may show green deposits. Plastic pipes should meet NSF International Standards for drinking water.

Are brass fittings, faucets or valves used in your facility? Brass is composed of two metals, commonly copper and zinc. Brass fittings used in drinking water taps / outlets often contain up to 8% lead. This is considered "lead-free" under the Safe Drinking Water Act. Contamination may still take place. The amount of lead that will leach from brass products with less than 8% lead is dependent upon the corrosiveness of the water and the processes employed in manufacturing the products. New brass may leach higher levels of lead until it passivates.

Type of taps / outlets used for drinking water? Components of the system, lead solders and lead in brass may all be sources of lead.

What are the brands and models of water coolers? Water coolers may be a major source of lead contamination. Under the Lead Contamination Control Act of 1988, water coolers with lead-lined tanks are considered to be imminently hazardous consumer products, and manufacturers and importers are to repair, replace or recall these coolers. Limits for solder, flux, and storage tank interior surfaces in contact with drinking water may not contain more than 0.2% lead. Other parts of water coolers that may come in contact with drinking water are not to contain more than 8% lead. The law attaches criminal and civil penalties for the manufacture and sale of water coolers containing lead.

Do faucets have accessible screens and when were they cleaned? Lead-containing sediments that are trapped on screens can be a source of significant contamination. Sediments may need to be tested, and screens should be cleaned frequently.

Are there signs of corrosion? Corrosion may indicate high levels of lead, copper and iron in the water.

Is electrical equipment grounded to water pipes? Electric current traveling through the ground wires may accelerate the corrosion of interior plumbing containing lead. DO NOT remove the wires from the pipes unless a qualified electrician installs an alternative grounding system. Improper grounding of electrical equipment may cause severe shock.

When was the water in your facility tested for contaminants? Results of water quality testing can provide clues about the corrosiveness of the water. If your facility operates its own water supply, such tests can help you decide on effective treatment approaches.

APPENDIX G. EXAMPLE SAMPLING PROTOCOL

Presented below are the general procedures for collecting samples of water for lead testing. Some environmental service providers and environmental laboratories will provide on-site sampling. Sampling by school or child care personnel is also an option. All personnel who assist in sampling should be adequately trained in proper sampling procedure, including site-specific record-keeping requirements. The following is a generic sample collection protocol.

Sample Containers

Obtain sample containers from the laboratory that will be performing the lead analysis.

> **Caution**
>
> Only use containers from a certified laboratory.

Sample Collection

Be certain to carefully follow the instructions provided by the laboratory.

1. Collect all water samples before the facility opens for the day and any water usage occurs.

> **Caution**
>
> Do not rinse the sample containers before filling.

2. The water must have sat in the pipes for at least 8 hours and not more than 18 hours before a sample is taken.

3. Do not collect samples after vacations, weekends or holidays.

4. Collect a 250-milliliter sample in the container provided by the laboratory from each outlet of interest without wasting any water before sampling the outlets.

5. Assign a unique sample identification number to each sample. Record that number on the recordkeeping form.

6. Accurately complete the recordkeeping form immediately following the collection of each sample. **Accurate information about the sample is essential.**

7. Ship the sample as instructed.

NOTES:

APPENDIX I. RESPONSE ACTIONS TO BE USED AFTER HIGH LEAD LEVELS ARE FOUND

Control Measures

Clean debris from all accessible screens frequently. If sediment is found in faucet screens, have the sediment tested by a laboratory and continue to clean screens frequently.

Use only cold water for food and beverage preparations in cafeterias and cooking classes. Hot water will dissolve lead more quickly than cold water and is therefore more likely to contain increased lead levels.

Turn off water to the tap / outlet using available valves or by capping the water line to taps / outlets where elevated levels of lead are identified. When taking this approach, the facility must continue to meet applicable codes for availability / accessibility of drinking water within the facility.

EPA guidance, Lead in Drinking Water in Schools and Non-Residential Buildings, provides specific recommendations for assuring adequate turn over of water in facility plumbing (see pages 31 and 32 of the guidance document). The following is a brief summary of that guidance.

- Flush the piping system in the facility.

  First-flush water that has been in contact with the facility plumbing for more than six hours should not be consumed. Flushing involves opening all suspect taps / outlets every morning before the facility opens and letting the water run for a period of time to clear water standing in the interior pipes and taps / outlets.

  Locate the tap / outlet farthest from the service line on each wing and floor; open the tap / outlet wide and let the water run for 10 minutes. For precise results, calculate the volume of the plumbing and flow rate -- exact determinations likely require assistance from a plumber or engineer.

  Open all valves at all drinking water fountains without refrigeration units and let the water run for one minute.

  Let the water run on refrigerated water fountains for 15 minutes. Because of the long time period required, routine flushing of these units may not be practical. Replacing them with lead-free units may be necessary.

  Open all kitchen taps / outlets (and any other taps /outlets used for drinking and/or cooking purposes) and let water run for one minute.

- Consider providing bottled water. This can be an expensive alternative. If this is the selected option, obtain a written statement from the bottled water distributor guaranteeing that the bottled water meets FDA and state standards.

  If provided, procedures on the use and care of dispensers/bottles must be developed and implemented. A very good source of information on this topic (and other topics related to lead in schools) can be found on the website of the Massachusetts Department of Environmental Protection at: http://www.mass.gov/dep/brp/dws/ lead.htm. Taking steps

such as using disposable bottles or refillable bottles that have been properly cleaned are essential to assuring a safe water supply.

Long-Term Remedies

There are a number of long-term actions that might reduce or eliminate sources of lead contamination that originate in a facility's plumbing. The results of testing will provide information that will help determine which treatment options will be most appropriate for individual circumstances.

While flushing individual or all taps / outlets may be a long-term solution, it does involve a potential for wasting water, which is particularly of concern in communities that are seeking to encourage conservation. While it is a quick and easy method, with nothing to install, flushing can be time-consuming for staff. There is also a risk of forgetting that the water is flowing. This process would also require that someone be responsible for follow-up to ensure that procedures are properly followed and are effectively reducing lead levels.

Time-operated solenoid valves can be installed to automatically flush the main pipes. However, these solenoids are not practical for flushing water coolers. Water coolers can be flushed continuously, using a needle valve, a drain and an air gap or flushed manually.

If the source of lead contamination is localized or limited to a few taps / outlets, replacing the taps / outlets might be the most practical solution. A tap / outlet may be replaced with a new one if the existing tap / outlet is suspected to be the contamination source. Metallic fixtures, even new ones, may contain up 8% lead and still be recognized as "lead-free". If you choose a solution that requires work by a plumber on any part of the facility's plumbing system, make sure the plumber uses only "lead-free" solders and materials. The SDWA of 1986 requires only "lead-free" materials be used in new plumbing and plumbing repairs.

Water that is soft or acidic can be treated to make it less corrosive. Corrosion control devices for individual buildings are commercially available. Installation of corrosion control treatment is generally not recommended because of the degree of operator skill and maintenance required. Further installation of treatment may redefine the facility as a "Public Water System," which makes it subject to SDWA regulations. Carbon, sand, cartridge filters and water softeners will not prevent corrosion.

Lead levels can be reduced at the tap / outlet. Reverse osmosis and distillation units are commercially available and can be effective at removing lead. These devices do make water corrosive and should be used only when placed at the tap / outlet. Facility managers should obtain information about these devices by writing or calling: National Sanitation Foundation International (NSF), 789 Dixboro Road, P.O. Box 130140, Ann Arbor, MI 48113-0140, (800) 673-6275.The device should be approved as meeting NSF Standard 53, NSF Standard 58 or the equivalent. It must be installed, operated, and maintained in accordance with manufacturer's recommended procedures. Proper operation and maintenance is essential.

Develop an alternative grounding scheme for electrical wires attached to internal plumbing systems to avoid acceleration of corrosion by electrical currents.

APPENDIX J. EXAMPLE MAINTENANCE CHECKLISTS

Maintenance Checklist

Name of Facility: _____

Address: _____

_____

Contact Name: _____

Phone #: (_____) _____

ACTIVITY TO BE EVALUATED	Yes	NO	Action
Plumbing Related to Drinking Water Fixtures			
Plumbing survey has been conducted?			
Alterations made to existing plumbing system?			
Certified components/materials used?			
Licensed plumber for the installation/modifications/alterations?			
Drinking/cooking outlets flushed at the start of each school day?			
Drinking Fountains			
Drinking fountains checked for known lead-containing models?			
Drinking fountains on the list of known lead-containing models removed?			
Collection/testing of water samples for lead has been implemented?			
Remedial actions implemented for fountains exceeding the action limit?			
Fountains exceeding the action limit after remedial actions removed?			
Cafeteria (if applicable)and Cooking Classes (if applicable)			
Faucets included in a regularly scheduled sampling/testing program?			
Only cold water is used for preparing foods and beverages?			
Bottled Water (if used) Water (if used)			
Bottled water is a substitute for devices taken out of service?			
Bottled water supplier approved by Arizona Department of Health?			
Bottled water stored in a safe, secure area?			
Dispensers cleaned regularly?			
Record Keeping			
Drinking Water Testing/Quality Records in a centralized and clearly labeled file?

APPENDIX K. EPA BROCHURE "IS THERE LEAD IN THE DRINKING WATER?"

How does lead get into water?

Lead enters the water ("leaches") through contact with the plumbing.

Lead leaches into water through:

- Corrosion of
  - Pipes
  - Solder
  - Fixtures and Faucets (brass)
  - Fittings
- Particles caught in aerators

Water characteristics, such as pH, hardness and temperature, affect the amount of leaching.

Why should we test the water?

Lead is a health risk to infants and children.

Exposure to lead is a significant health concern, especially for pregnant women, young children and infants, whose growing bodies tend to absorb more lead than the average adult. Drinking water is one possible exposure route for lead. A dose of lead can have a big effect on a little body, especially an infant whose diet is mostly liquid.

The longer water remains in contact with leaded plumbing, the more opportunity exists for lead to leach into the water. Facilities with prolonged periods of no water usage, such as schools and day cares, may have elevated lead concentrations in the water.

Many children spend a significant part of their days at school or in a child care facility. The fixtures that provide water for consumption, including drinking, cooking lunch, and preparing juice and infant formula, should be tested.

Testing is the only way to confirm if lead is present or absent.
Lead solder with more than 0.2% lead and plumbing with more than 8% lead were banned in 1987. Buildings did not have to be built with certified "lead-free" fixtures until 1997. Even new, certified components can leach some lead.

Water System tests do not give the whole picture.

Most water systems test for lead as a regular part of water monitoring. These tests give a system-wide picture but do not reflect conditions at a specific drinking water outlet.

How do we participate in the lead-free drinking water program?

- Develop a sampling plan.
- Take water samples.
- Use a certified lab to analyze water samples.
- Replace outlets with lead-free components, as necessary.

EPA's guidance, "Lead in Drinking Water in School and Nonresidential Buildings" and "Sampling for Lead in Drinking Water in Nursery Schools and Day Care Facilities," can help schools and day cares achieve lead-free drinking water. Obtain these documents through www.epa.gov/safewater/Pbhs

See this site for more tools to help achieve lead-free drinking water: www.epa.gov/safewater/lead/schools/index.html

What can I do to reduce lead risk at my home?

- After the water is stagnant for several hours, flush pipes until you feel the temperature change before cooking, drinking, or brushing teeth.
- Use only cold water for cooking and drinking. Never cook or mix infant formula using hot water.
- Have your water tested.

Is there lead in the drinking water?

You can reduce the risk of lead exposure from drinking water in educational facilities.

Lead-Free Drinking Water
In Schools and Day Cares

APPENDIX L. QUESTIONS AND ANSWERS – LEAD IN DRINKING WATER

Q: How does lead get into water?

A: Lead generally enters drinking water after contact with a building's plumbing system. Lead may be present in the components of the plumbing system such as lead solder, brass fixtures and lead pipes. The amount of time the water is in contact with the lead components of the plumbing system is typically the factor that contributes most significantly to the amount of lead in the water supply.

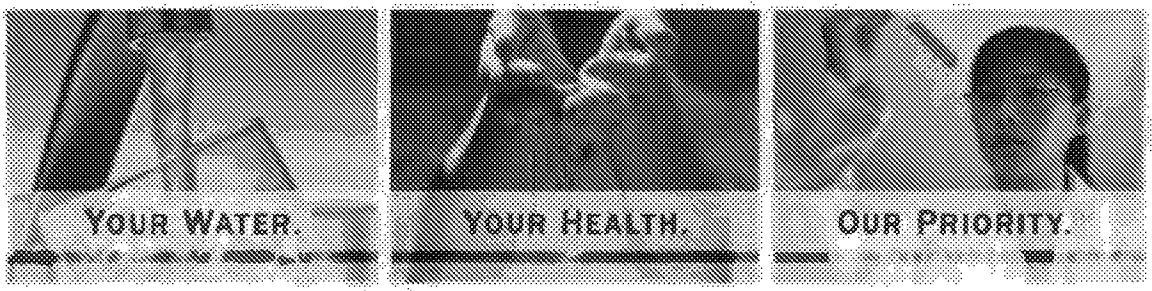
Q: Why should we test the water?

A: The only way to determine how much lead is present in the drinking water in your facility is to have the water tested for lead.

Q: Why is lead a health concern?

A: Lead is a toxic material that is known to be harmful to humans if ingested or inhaled. Lead can cause damage to the brain, kidneys, nervous system and red blood cells. Children, infants, pregnant women and their unborn children are especially vulnerable to the harmful effects of lead. Lead has been associated with impaired mental and physical development in children.

Q: How are children exposed to lead?



A: Children can be exposed to lead from a number of sources, including lead-based paints in housing built prior to 1978, lead-contaminated dust and soil and drinking water. Drinking water typically is not the primary source of exposure to lead for children.

Q: Why is lead a special concern for schools and child care facilities?

A: Children are more vulnerable to the effects of lead exposure. Growing children will also absorb the lead that they consume more rapidly than adults. In addition, children at play may come into contact with more sources of lead, such as dirt and dust, than adults.

Q: At what level does the U.S. EPA recommend taking action on lead results from water in schools?

A: The U.S. EPA recommends taking action if lead levels in drinking water in schools at 20 parts per billion or greater.

STRAIGHT Talk Lead in Water

The U.S. Environmental Protection Agency (EPA) notes that "the greatest exposure to lead is swallowing or breathing in lead paint chips or dust." However, while lead is rarely present in water coming from a treatment plant, it can enter tap water through corrosion of some plumbing materials. Lead builds up in the body over many years and can cause damage to the brain, red blood cells and kidneys. The greatest risk is to young children, pregnant women and their unborn babies.

- Since 1992, all public drinking water systems are required to regularly test a sample of high-risk homes for lead at the tap.
- If the results from lead testing exceed the EPA "action level" of 15 parts per billion in more than 10 percent of homes tested, individual water utilities are required to notify area residents via newspapers, radio, TV and other means.
- In instances of high lead levels in water, the most common sources are lead-based solder used to join copper pipe, faucets made of brass and chrome-plated brass, and in some cases, pipes made of lead that connect a home to the water main.
- In 1986, Congress banned the use of solder containing more than 0.2% lead and restricted the lead content of faucets, pipes, and other plumbing materials.

Concerned residents can take several steps to limit possible exposure:

- You can't see, smell or taste lead in your water. Testing at the tap is the only way to measure the lead levels in your home or workplace. If you choose to have your tap water tested, be sure to use a properly certified laboratory. Testing usually costs between $20 and $100.
- Flushing your water tap clears water from your plumbing and home service line to ensure you are getting drinking water from the main, where lead is rarely present. Let the water run from the tap until it is noticeably colder (this may take two minutes or more) before using it for cooking or drinking. Flushing the tap is particularly important when the faucet has gone unused for more than a few hours.

The Authoritative Resource on Safe Drinking Water

- Some home treatment devices remove lead, but not all do. Before you purchase a home treatment device, you should verify the manufacturer's claims. A good resource to assist you is NSF International — www.nsf.org. Once a treatment device is installed, make sure it is properly maintained.
- Use only cold water for cooking or drinking. Lead leaches more easily into hot water than cold water. Boiling water DOES NOT remove lead.
- Consult with your family doctor or pediatrician to receive a blood test for lead and learn more about the health effects associated with exposure.

Issue Backgrounder

Lead in Drinking Water

Where does lead come from?

- Lead is a naturally occurring metal that was used regularly in a number of industrial capacities for most of the 20th century. We no longer use lead in many of these products, but lead from older products remains.
- The U.S. Environmental Protection Agency (EPA) and the U.S. Centers for Disease Control (CDC) report that lead paint (and the contaminated dust and soil it generates) is the leading source of lead exposure in older housing. Lead has been used as a component of paint, piping (including water service lines), solder, brass, and until the 1980s, as a gasoline additive.

Why is lead a health concern?

- Lead builds up in the body over many years and can cause damage to the brain, red blood cells and kidneys.
- The greatest risk is to young children, pregnant women and their unborn babies. Amounts of lead that won't hurt adults can slow down normal mental and physical development of children, particularly those under 6 years old.
- At high levels of contamination, lead can damage adults' kidneys and reproductive systems. And at extremely high levels, lead poisoning can cause mental retardation, coma, convulsions and death.
- A child at play can come into contact with sources of lead contamination – such as dirt, dust and paint chips – that rarely affect an adult. It is important to wash children's hands and toys often, and to try to make sure they only put food in their mouths.
- For more information on lead contact the visit www.cdc.gov or contact Jennifer Sarginson of the CDC's Lead Poisoning Prevention Branch at (404) 498-0694.

Where does lead in drinking water come from?

- Lead contamination is rarely found in sources of water such as rivers, wells and reservoirs. It's almost never present in water leaving a treatment plant or traveling through water mains.
- EPA estimates that 10 to 20 percent of human lead exposure may come from drinking water, and infants who consume mostly mixed formula may receive 40 to 60 percent of their lead exposure from drinking water.
- The most common sources of lead in drinking water are lead-based solder used to join copper pipe, faucets made of brass and chrome-plated brass, and in some cases, pipes made of lead that connect a home to the water main (service lines).

- Lead enters drinking water as a result of corrosion, as water comes into contact with lead materials over a period of time. If standing water is in contact with lead materials for several hours, the water may accumulate lead levels that are of concern.
- Water providers adjust their treatment procedures to achieve "optimized corrosion control," which significantly reduces the amount of lead leaching into the water.

What is the Lead and Copper Rule?

- The Lead and Copper Rule provides a framework for utilities to a) determine if their corrosion control program is effective at limiting lead exposure; b) take additional steps to protect public health; c) and ensure consumers are notified if the utility finds lead above the action level in the community.
- The Lead and Copper Rule is based on a "treatment technique" requirement in which the lead action level is a trigger – the action level is not health based.
- Monitoring under the LCR takes place at worst-case sampling locations as samples are taken of water standing overnight in homes where lead pipe or lead solder is present.
- If the results from lead testing exceed the EPA "action level" of 15 parts per billion in more than 10 percent of homes tested, individual water utilities are required to notify area residents via newspapers, radio, TV and other means.
- EPA's most recent data confirms that the elevated lead levels in Washington, D.C., are not common nationwide. More than 96 percent of utilities reporting data do not exceed the 15-parts-per-billion action level for lead. (http://www.epa.gov/safewater/lcmr/lead_data.html)

How is the water community responding to issues of lead in drinking water?

- The drinking water community supports the thorough examination of the situation in Washington, D.C. and the Lead and Copper Rule, which EPA is now undertaking.
- The American Water Works Association has testified before U.S. Congressional committees about this subject. Testimony is available at: http://www.awwa.org/Advocacy/govtaff/legislat/leg_test.cfm
- EPA is hosting a series of workshops to further study all aspects of lead in drinking water, including recent sessions on public communication of lead issues and lead in schools.
- The American Water Works Association has convened working group of utility professionals examining the lead in drinking water issue and identifying best practices.

How can consumers protect themselves from lead in drinking water?

While water providers have taken steps to limit lead in drinking water, consumers can take the following steps if concerned about lead exposure:

- Find out about lead testing results in their community. Each utility's annual Consumer Confidence Report contains information on lead monitoring conducted under the Safe Drinking Water Act. If they do not have a Consumer Confidence Report, they can contact their utility for a copy.
- You can't see, smell or taste lead in your water. ***Testing at the tap is the only way to measure the lead levels in your home or workplace.*** If consumers choose to have their tap water tested, they should use a properly certified laboratory (they can call their utility to obtain a list). Testing usually costs between $20 and $100.

- Flushing the water tap is a simple method to help avoid high lead levels. Flushing clears water from the plumbing and home service line to ensure the drinking water comes from the main, where lead is rarely present. Let the water run from the tap until it is noticeably colder (this may take two minutes or longer) before using it for cooking or drinking. Flushing the tap is particularly important when the faucet has gone unused for more than a few hours, because the longer water resides in home plumbing, the more lead it may contain.
- Flushing the tap may not be effective in reducing lead levels in high-rise buildings. If those consumers are concerned about lead in their drinking water, they should talk to their landlord or consult their local health department about ways to minimize exposure.
- Use only cold water for cooking or drinking. Lead leaches more easily into hot water than cold water. Boiling water DOES NOT remove lead.
- A licensed plumber can determine if a home contains lead solder, lead pipes or pipe fittings that contain lead. A plumber can also determine if a home has a lead service line connecting home plumbing to the community water system's water main. The presence of these materials does not mean lead is in the water, but that the potential for lead in the water exists.
- Make sure that repairs to copper piping do not use lead solder.
- Some home treatment devices remove lead, but not all do. Before purchasing a home treatment device, consumers should verify the manufacturer's claims. A good resource is NSF International (www.nsf.org).
  Once a treatment device is installed, make sure it is properly maintained. Using bottled water is also an alternative. (Information on the lead levels in bottled water is available from bottled water manufacturers.)
- Consult with the family doctor or pediatrician to receive a blood test for lead and learn more about the health effects associated with exposure. CDC recommends all children be tested for lead.

Overview of Awwa Research Foundation (AwwaRF) Lead Research

The water community has been studying corrosion control and its impact on lead in drinking water for many years. Below is a list of studies from AwwaRF, a member-supported, international, nonprofit organization that sponsors research to enable water utilities, public health agencies, and other professionals to provide safe and affordable drinking water to consumers.

One of the most important lessons learned from the AwwaRF research conducted on lead and copper corrosion is that every utility's lead and copper corrosion challenges are unique to that utility's source water quality, treatment train, and distribution system configuration and materials. There is no standard "recipe" for lead and copper corrosion control that every utility can apply regarding treatment strategies, corrosion control strategies, or distribution system management.

Areas of AwwaRF Research:

Corrosion Control Effects on Water Quality and Corrosion

Distribution system Water Quality Changes Following Corrosion Control Strategies (2000)
A General Frame Work for Corrosion Control Based on Utility Experience (1997)
Role of Phosphate Inhibitors in Mitigating Lead and Copper Corrosion (2001)

Treatment Process Effects On Lead and Copper Corrosion
Chloramine Effects on Distribution Systems Materials (1993)
Optimizing Chloramine Treatment (Currently in publication)
Impacts of Enhanced Coagulation on Corrosion of Water Treatment Plant Infrastructure (2004)
Disinfectant Decay and Corrosion: Laboratory and Filed Studies (2004)

Specific Water Chemistry Effects on Lead and Copper Corrosion
Corrosion and Metal Release for Lead Containing Plumbing Materials (1999)

Tools to Help Utilities Manage Lead and Copper Corrosion Issues
Development of a Pipe Loop Protocol for Lead Control (1994)
Optimizing Corrosion Control in Water Distribution Systems (2004)
Post-Optimization Lead and Copper Monitoring Strategies (2004)
Lead Pipe Rehabilitation and Replacement Techniques (2000)
Lead Control Strategies (1990)

MDEQ - Governor's Office Briefing - City of Flint Drinking Water (Draft)

What contributed to the Boil Water Advisories in the City of Flint?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWA's) in the City of Flint during August and September 2014. While use of the Flint River has increased the amount of natural organic matter in the City's water, the City's water treatment plant (WTP) has performed well above treatment requirements for organic carbon removal. In addition, less than 20% of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the City, rather than in such a localized area.

The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30%, has seen even greater losses since February due to an increase in cold weather related water main breaks and leaks. The City lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWA were found to be closed during the City's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure. One of these valves has remained broken.

The BWA's also occurred during the warmest and for 2014 relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

Process for Issuance and Cancelation of a Boil Water Advisory

There are a number of conditions that can trigger boil water advisories. This includes the following:

- Bacteria Monitoring Detections
- Bacteria Standards Violations
- Treatment System Failures
- Waterborne Disease Outbreaks
- Loss of System Pressure
- Water Main Breaks
- Other Interruptions in Service

The DEQ has developed policy regarding BWAs to help guide staff, provide consistency, and maintain public health. A copy of DEQ policy ODWMA-399-022 is attached.

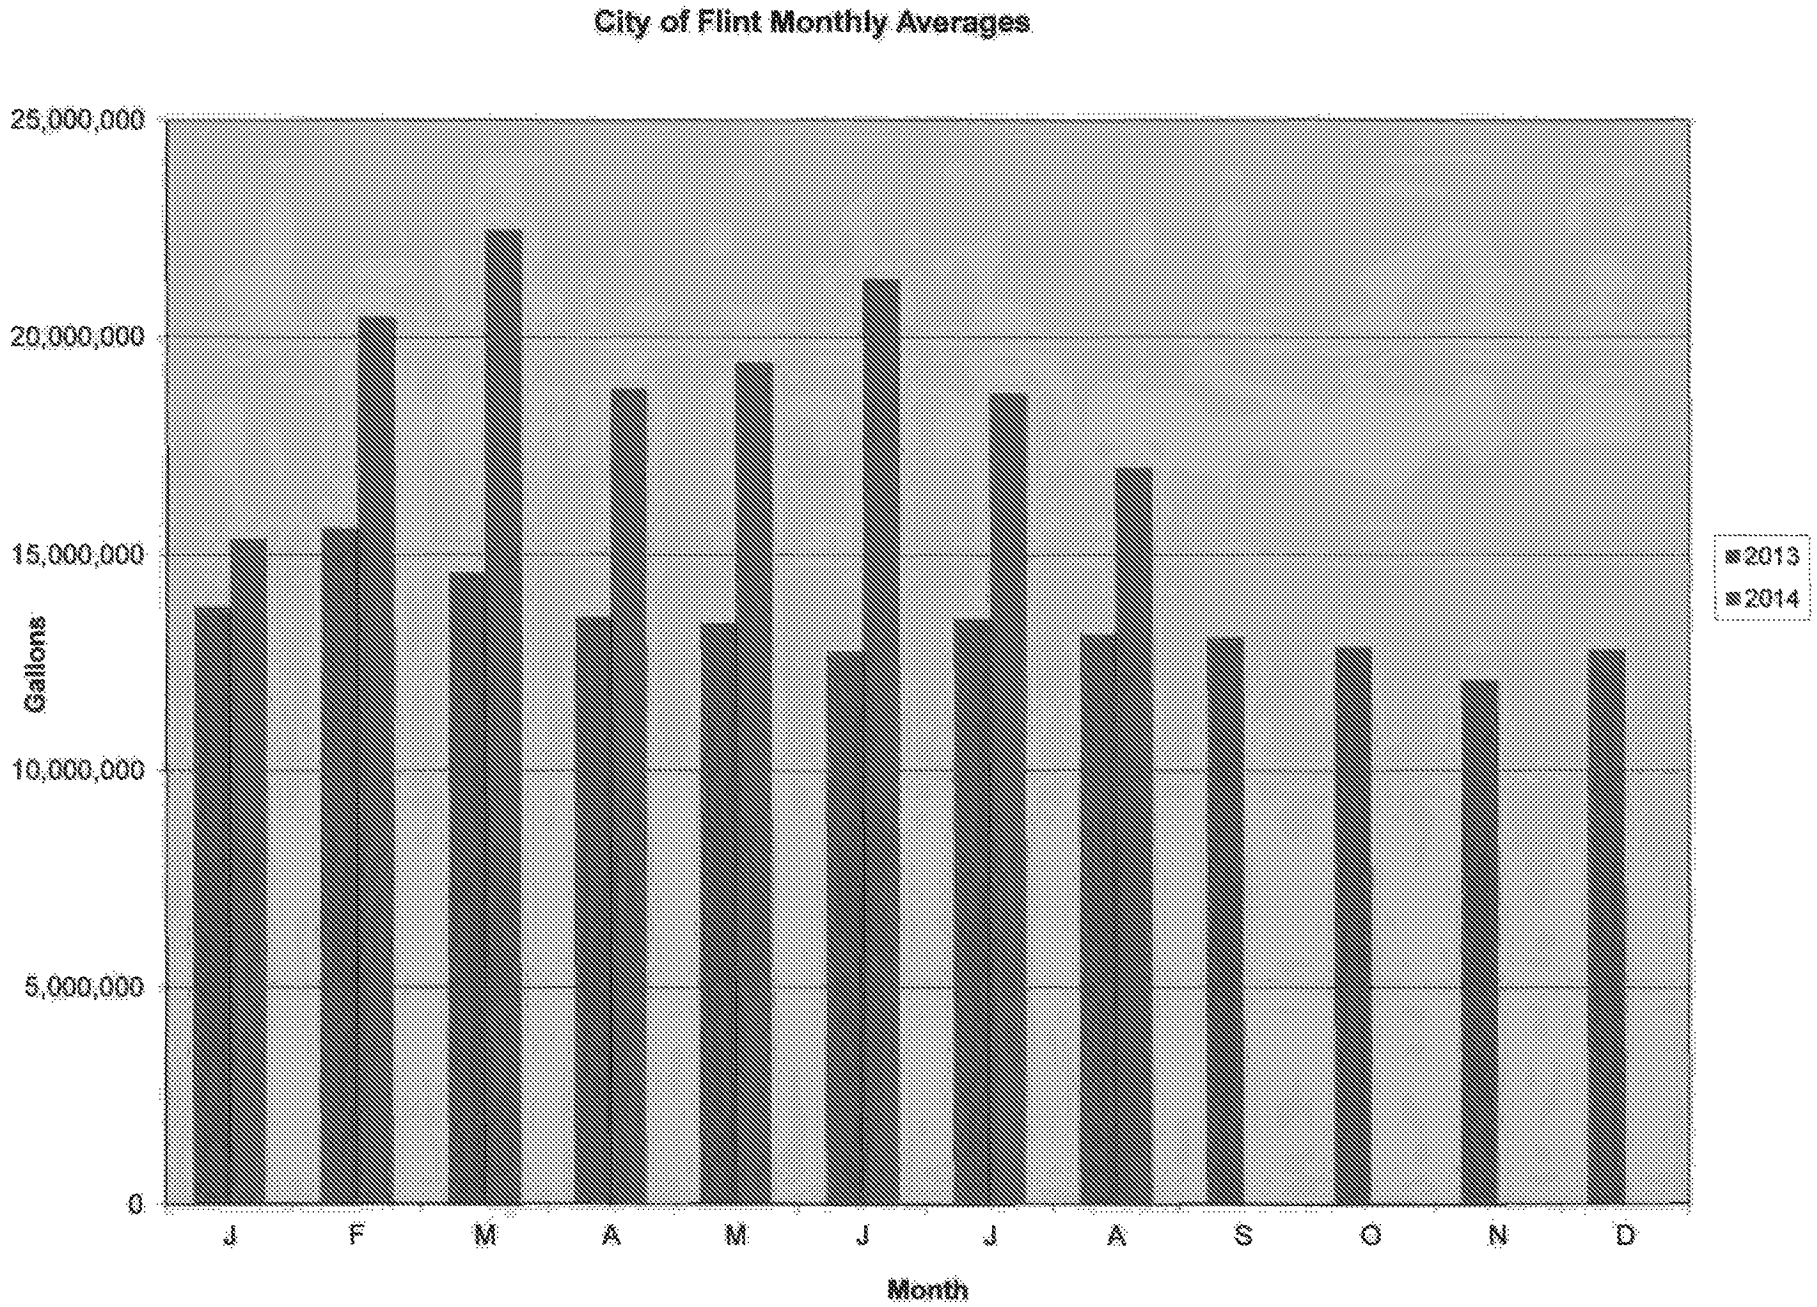
BWA's may be self-initiated by the water system, issued collaboratively in consultation with the DEQ, or when necessary mandated by the DEQ. Requesting customers to boil the water when bacterial contamination has occurred provides an added barrier of public health protection.

The BWA's which recently occurred in the City of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City of Flint collaboratively in consultation with the DEQ.

Current regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the EPA, have been in effect since 1990, and incorporated into the Michigan Safe Drinking Water Act. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for Total coliform and E.coli. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system minimizes the likelihood that pathogens are present. E.Coli is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for a period of 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

Recent History of City of Flint Water System



Historically the City of Flint had been a customer of the Detroit Water and Sewerage Department (DWSD) while simultaneously maintaining the City of Flint WTP to provide emergency backup service using the Flint River. The WTP performed quarterly test operations to maintain readiness and was utilized twice in 2009, supplying water once for 2 days and the other for 3 days.

In April 2013, the City of Flint notified DWSD that it would be terminating service in the future and contracting for raw water service from the Karegnondi Water Authority (KWA). Work on the KWA pipeline from Lake Huron broke ground in June 2013 and is expected to be completed with connection in late 2016.

In August 2013, Rowe Professional Services Company completed an engineering proposal for improvements to the City of Flint WTP that would allow continuous operation of the WTP utilizing the Flint River in lieu of continuing service from DWSD until completion of the KWA pipeline. In March 2014, the City of Flint entered into a Consent Agreement with the DEQ regarding the Flint WTP lime sludge facility. In April 2014, the DEQ issued a construction permit for improvements to the Flint WTP. On April 25, 2014 the City of Flint began continuous operation of the WTP, using water from the Flint River and discontinued the purchase of water from DWSD.

A BWA was issued from August 15–20, 2014, for a portion of the City of Flint due to localized detections of Total Coliform and E.Coli bacteria. Another BWA was issued from September 5-9, 2014, due to localized detections of Total coliform bacteria in the same and adjacent portions of the City of Flint. The advisory covered an area approximately 6 square miles. The City of Flint has a total land area just over 34 square miles.

While many of the BWA contributing factors listed above require long term solutions, the City has taken operational steps to limit the potential for a BWA to reoccur. The City has increased flushing of water mains to limit residence time, maintain disinfectant residual, and help remove buildup and deposits within the piping. The City is boosting chlorine disinfectant residual at locations in the distribution system as needed. The City continues to investigate water leaks, water main breaks, and the status and condition of system valves.

City of Flint, Michigan
Office of the City Administrator

Memo

To: Dayne Walling, Mayor

From: Natasha L. Henderson, City Administrator

cc: President Freeman and Councilmembers

Date: October 20, 2015

Re: Water Filtration Plant and Water Distribution Internal Review

---

Water Filtration Plant and Water Distribution Systems Overview

The City of Flint's water filtration plant and distribution system have experienced many challenges over the past two years and it is of grave concern that we reflect upon the decisions that have been made and understand how we will proceed in the future. First, and foremost the City will conduct an internal review of the steps that were taken in 2013 when the agreement with Karegnondi Water Authority (KWA) was signed.

In the wake of recent water concerns, I have developed a proactive and comprehensive plan showing the City's commitment to deliver high quality water, address its aging infrastructure, and maintain a qualified staff. I am outlining a series of steps that the city will take to not only ensure that these goals are met but a plan that is designed to start rebuilding community trust through action and transparency.

In addition, with the assistance of the EPA Task Force, Michigan Department of Environmental Quality, and Safe Drinking Water Technical Advisory Committee, the following steps are meant to go into effect as quickly as possible with all goals being accomplished by the time KWA begins delivering raw water.

- Independent review
- Processes & Testing
- Training

- Technology
- Communication
- Lead Lines
- Capital Improvements

Independent Review

We will seek to commission an independent source to review the technical and operational steps that occurred from the time the City signed on to the KWA to present. This is meant to internally perform an after action review in order to clearly assess the decisions that were made. My expectation is that we will hire out-side legal counsel to lead this internal review. I believe it is imperative that the City has all information that has led the City to the water quality issues that have arisen.

Internal Processes & Testing

We understand that EPA standards are the minimum requirements that utility systems are required to meet, the City will establish and move forward with higher standards and goals than those set by regulators. As these new standards are set, they will be published with a plan on how to obtain each goal complete with expected timeframes. The following are the first set of goals that have been set by the City that exceed the regulatory requirements.

Regulatory Requirements	City Goals
(1) F-1 Licenced Personnel	(2) F-1 Licenced Personnel
(1) S-1 Licensed Personnel	(2) S-1 Licensed Personnel
100 TTHM Samples per Month	120 TTHM Samples per Month
100 Lead/Copper Volunteer Samples / yr.	300 Lead/Copper Volunteer Samples / yr.
Annual Water Quality Report	Quarterly Water Report

Training

We will encourage all utility employees to become members of the American Water Works Association (AWWA) which is the largest nonprofit, scientific and educational association dedicated to managing and treating water. The AWWA offers continual training opportunities and the City will develop an internal training regimen that employees must adhere to. The goal is to continue to develop each employee which promotes a long term succession plan.

Technology

The addition of enhanced Supervisory Control and Data Acquisition (SCADA) will make sure that the system is running with the industries most updated technology and running as efficient as possible. The SCADA adds automation to the Water Plant thereby reducing the need for as much manual intervention. The City will also maintain Safe Drinking Water Technical Advisory Committee with more consistent meetings.

Enhanced Communication

We recognize that one of the key features of a Utility is the public communication with honest and candid information. We will increase the way we send information to people and the frequency that our communication is available. The following are first steps in that direction.

- Monitors around City Hall that display information about the water system

- Direct emails to individuals and neighborhood groups informing people where work is occurring
- Door hangers for field workers to distribute alerting people when water may be off or discolored
- A website page and GIS map dedicated to water events
- Quarterly Water reports that are directly mailed to users
- More frequent press releases that provide information relating to infrastructure concerns
- Immediate notification using all of the above media if a violation occurs
- An answering service so that every call is answered in a timely manor

Lead Service Lines

Every effort will be made to ensure a program will is in place to address the long-term goal of replacing all lead service lines. The program is expected to address the location of all City owned lead service lines and look to provide an opportunity for homeowners to receive a grant in order to have their service line changed at the same time as the city is changing its lines. This coordinated program will look to utilize funds from multiple avenues to support City residents, such as:

- CDBG Funds
- DWRF revolving loan funding
- Grant funding

Capital Improvement Plan

The City will continue to modify its 5-year CIP annually to make sure that we are always addressing the most critical issues facing the City. Another rate study will help set the correct rate for the system and determine the proper allocation to address concerns. The Water Reliability Study will continue to highlight the critical needs and will continue to be updated every two years.

As City Administrator, my goal is to ensure all of the necessary steps are in place prior to the implementation of KWA delivering water to the City. All of these initiatives will be inserted into the Utilities strategic plan and tracked regularly by staff, myself, and reported to the DPW Committee to ensure accountability.

Subject: FW: Flint Draft Response

At 1:30 today Mike Prysby and I attended an unplanned conference call between Director Wyant and Treasurer Dillon. Prior to the conference call I provided the director what I had put together at that point (see email below).

There was follow up discussion with the Director following the call and in addition to the response below he would like us to be prepared to discuss the following points:

1. Can we say to Treasury that KWA is a cost effective option?
2. Can we say to Treasury that DWSD is a cost effective option?
3. Regulatory authority to allow/prevent water system breakups and local vs. state decisions about associated costs
    a. Besides Benton Township and Norton Shores/Fruitport what other systems have pulled out of a regional system and what were the DW regulatory considerations?
4. How do/can we assess the dollar value on the benefits of a DWSD Regional water system vs. the cost differential?
    a. In the TYJT report, the status quo option for Flint with DWSD vs. KWA cost estimate differential is $172 million.
5. What unanswered questions do we have about the DWSD options in the TYJT report?
    a. 8/12 Blend
    b. 12/8 Blend

I am still planning on a ODWMA meeting/conference call tomorrow morning at 9:00 to address the above and addend any additional comments before I provide a final response to the Director Wednesday afternoon in preparation for Thursday meetings.

Call me if you have any questions.

Cc: Willard, Veronica (DEQ); Shekter Smith, Liane (DEQ)
Subject: Flint Draft Response

Director Wyant,

In preparation for our call today with Treasurer Dillon's office, ODWMA has developed the following for consideration. We can provide any additional info you require during the meeting.

ODWMA has reviewed the materials developed by the consultant Tucker, Young, Jackson, Tull, Inc. (TYJT) for Treasury regarding the City of Flint and potential alternatives for public water supply. Based on our reviews, we have developed the following comments to this point in our analysis:

1. The TYJT report does not contain the full scope of the Karegnondi Water Authority (KWA) raw water supply system. TYJT concerns over raw water supply redundancy and reliability are addressed to the satisfaction of ODWMA under the full

KWA proposal. Please note some portions of the overall project are being financed independently by the Genesee County Drain Commission.

2. There are significant differences in contract language between KWA and Detroit Water and Sewerage Department (DWSD) with respect to the contracted maximum day demand capacity.
    a. Under a KWA contract, a "maximum day" capacity of 18 million gallons per day (MGD) would fully satisfy current demands of the City of Flint, without the need to supplement raw water capacity using the Flint River. (18 MGD, average over a 30 day period).
    b. Under a DWSD model contract, a "maximum day" capacity, even at 18 MGD, would not satisfy the current demands for the City of Flint. (18 MGD, over any 24 hour period).

3. Restrictions in contracted capacity that would prevent the City of Flint from meeting peak demand requirements present potential limits to economic development within the City of Flint, including possible connection bans and water system extension bans. This information was previously conveyed to the City of Flint by ODWMA staff.

4. All contract options with DWSD that are considered semi-competitive with the KWA contract do not fully supply the City of Flint, and would require the City of Flint to meet a significant, if not majority, of its water demands by treating water from the Flint River. Continuous use of the Flint River at such demand rates would:
    a. Pose an increased microbial risk to public health (Flint River vs. Lake Huron source water)
    b. Pose an increased risk of disinfection by-product (carcinogen) exposure to public health (Flint River vs. Lake Huron source water)
    c. Trigger additional regulatory requirements under the Michigan Safe Drinking Water Act (LT2ESWTR)
    d. Require significant enhancements to treatment at the Flint WTP, beyond those identified in the TYJT report (see item X below).
    e. Water Resource Division is evaluating potential impacts to NPDES wastewater discharge permits in downstream segments of the Flint River.

5. The TYJT report does not adequately address increased requirements and costs associated with using the Flint River as a significant source for the Flint WTP, which are not necessary under a Lake Huron source water scenario. This includes:
    a. The need to provide softening treatment
    b. Limitations on disposal options for lime softening sludge
    c. Increased ozone capacity, UV disinfection
    d. Additional backup power, more power required for Flint River operation

6. The Flint WTP must operate at some minimum level and within a range of flow rates to maintain treatment effectiveness. Currently that minimum level is 9 MGD. This level may be reduced with additional capital costs to modify the WTP, not addressed in the TYJT report.

7. Allowing Flint WTP to blend water with DWSD sets a new precedent that could pose future consequences with other DWSD customers.

8. Costs impacts to remaining DWSD customers would be similar under the proposed scenarios, only retaining 8 MGD of 30+ MGD total Flint/Genesee Co. demands, based on the following:
    a. Genesee County distribution system demands are pulling out of DWSD regardless of the decisions by Flint WTP
    b. Flint's need to utilize the Flint River as a source

9. ODWMA anticipates cost savings under the KWA proposal will be leveraged to provide additional improvements to the City of Flint water distribution system, improving efficiency and providing additional cost benefits.

10. Major cost discrepancies in TYJT analysis
    a. Engineering, Legal, Administration, Contingency – TYJT appears to have effectively double charged for these costs in their KWA estimates without adequate justification
    b. Pumping facilities – TYJT cost estimate methodology does not appear to address localized market costs and does not distinguish fixed and variable costs in its comparison analysis.

11. Remaining DWSD customers in Lapeer County could potentially see water quality impacts as a result of Flint joining KWA.
    a. City Lapeer
    b. City of Imlay City

Additional response to the TYJT report has also been provided by Rowe Engineering to Flint EFM, Mr. Ed Kurtz.

ODWMA has continued to meet on a regular basis with KWA, Genesee County, and the City of Flint regarding these water supply proposals.

ODWMA will continue to provide any additional detailed analysis requested by Treasury or the DEQ Executive Office.

DEQ	OFFICE OF DRINKING WATER AND MUNICIPAL ASSISTANCE POLICY AND PROCEDURE		DEPARTMENT OF ENVIRONMENTAL QUALITY
Original Effective Date: August 4, 2003 **Revised Date:** **Reformatted Date:** January 17, 2013	**Subject:** Lead and Copper Rule Implementation **Division/Office and Program Names:** ODWMA-Public Water System Supervision Program		**Category:** ☐ Internal/Administrative ☐ External/Noninterpretive ☒ External/Interpretive
	Number: ODWMA-399-027	**Page:** 1 of 9	

A Department of Environmental Quality (DEQ) Policy and Procedure cannot establish regulatory requirements for parties outside of the DEQ. This document provides direction to DEQ staff regarding the implementation of rules and laws administered by the DEQ. It is merely explanatory; does not affect the rights of, or procedures and practices available to, the public; and does not have the force and effect of law.

INTRODUCTION, PURPOSE, OR ISSUE:

The Lead and Copper Rule (LCR) of the National Primary Drinking Water Regulations was promulgated by the United States Environmental Protection Agency (U.S. EPA) under the federal Safe Drinking Water Act. The complexity of the rule necessitates guidance to maintain consistent implementation of the rule by field staff. Field staff include the Department of Environmental Quality (DEQ) public water supply (PWS) staff and local health department (LHD) staff. The LHDs oversee the Nontransient Noncommunity Water Supplies (NTNCWS) under authority delegated by the DEQ.

This policy replaces Water Division Policy and Procedure WD-03-019, Lead and Copper Rule Implementation, dated August 4, 2003.

AUTHORITY:

The following are the administrative rules promulgated under the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), related to the LCR (R 325.10101 *et seq.*):

- Rule 410 – Public Education and Consumer Notice of Lead Result
- Rule 604f – Corrosion Control Treatment, Source Water Treatment, and Lead Service Line Replacement
- Rules 710a, 710b and 710c – Monitoring
- Rule 710d – Reporting
- Rule 734 – Reporting of Results of Analyses
- Rule 1506 – Retention of Records

LIST OF ACRONYMS:

Act 399	Safe Drinking Water Act, 1976 PA 399, as amended
AL	Action Level
CCT	Corrosion control treatment
CDS	Combined distribution system
CDW	Community Drinking Water
CS	Consecutive Systems
CWS	Community Water Supply
LCR	Lead and Copper Rule
LHD	Local Health Department
MCS	Modified Consecutive System
mg/L	milligrams per liter
NPDWS	Noncommunity and Private Drinking Water Supplies
NTNCWS	Nontransient Noncommunity Water Supplies
OWQP	Optimal water quality parameters
PE	Public Education
POU or POE	Point of use or point of entry device
PWS	Public water supply
Rule 410	R 325.10410 and similarly throughout
WQP	Water quality parameters

DEFINITIONS:

"Improper sample" – a sample that does not meet all three of the following conditions as required in Rule 710a(2)(b):

- Sample that is one liter in volume.
- Sample that is first draw after the water has sat motionless in the plumbing for not less than six hours. Non-first draw samples may be allowed in facilities such as a prison or a hospital under Rule 710a(2)(e).
- Sample from either a:
  - Residential site cold water kitchen tap or bathroom sink tap, or
  - Nonresidential site interior tap typically used for consumption.

"Invalid sample" – a sample that meets one or more of the following conditions under Rule 710a(6):

- The laboratory establishes that improper sample analysis caused erroneous results.
- The sample container was damaged in transit.
- There is substantial reason to believe that the sample was subject to tampering.
- Field staff determine that the sample was taken from a site that did not meet sample site criteria as listed in Rule 710a(1)(c) to (e) and (h) for CWS and listed in Rule 710a(1)(f) to (h) for NTNCWS.

"Optimal water quality parameters (OWQP)" – the water quality parameters with limits, values, and dosages set by field staff under Rule 604f(3)(f) that represent optimal corrosion control treatment (CCT).

"Reduced number of sites" – the number of distribution system sites sampled for either:
- Lead and copper under the reduced monitoring column in the table in Rule 710a(3)(a) or
- WQP in Rule 710b(7)(a).

"Small, medium, or large water supply" – a water supply serving 3,300 or fewer people (small), greater than 3,300 and fewer than 50,001 people (medium), or more than 50,000 people (large), respectively.

"Standard number of sites" – the number of distribution system sites sampled for either:
- Lead and copper under the standard monitoring column in the table in Rule 710a(3) or
- WQP in Rule 710b(3)(a).

"Water quality parameters (WQP)" – parameters that are monitored for at the entry points to the distribution system and in the distribution system during the initial monitoring periods prior to CCT, during the follow-up monitoring period after CCT is installed, and during each six month monitoring period after field staff designate optimal CCT.

POLICY:

1. **Summary of Rule Requirements**

   Corrosion causes lead and copper to leach from pipes in the distribution system. The LCR requires water supplies to optimize CCT to minimize consumers' exposure to lead and copper in drinking water.

   Water supplies select and monitor distribution system sites that are most at risk of corrosion. Field staff may consider the small or medium water supply as having optimized CCT if results do not exceed the action level (AL) for lead of 0.015 milligram per liter (mg/L) and copper of 1.3 mg/L in 90 percent of sites tested during two consecutive six-month monitoring periods. Small and medium supplies that cannot demonstrate optimal CCT in two consecutive six month monitoring periods must commence CCT steps. All large water supplies must complete CCT steps, regardless of lead and copper levels. A water supply notifies consumers of the lead levels found at the site that was tested. Any supply that exceeds the lead AL must provide public education (PE) materials.

   Source water treatment or lead service line replacement may be required when an AL continues to exceed after installing CCT. This policy does not discuss source water treatment or lead service line replacement.

2. **Site Selection**

   a. Summary of Rule Requirements:
   Water supplies select distribution sites that are most at risk of corrosion and categorize each site as Tier 1, 2, 3 based on risk. If insufficient Tier 1, 2, or 3 sites are available, the sampling pool is completed with representative sites with plumbing materials

commonly found at other sites in the distribution system. As a site becomes unavailable, the site may be replaced provided the new site is selected based on Tier 1, 2, and 3 priorities. A replaced site should be explained when reporting on lead and copper monitoring.

b. Selecting Tier 1 Sites Based on Year Built:
Tier 1 sites are single family structures with:
   i. lead piping, or
   ii. lead service lines, or
   iii. copper piping and lead solder built after 1982 as per rule. It is believed that the corrosion may have stabilized in pipes of older structures built in 1982 or before, while newer pipes may continue to leach lead and copper for some time. However, due to a lead ban in 1987, structures built in 1987 or later were considered lead free. Therefore, Tier 1 sites with copper piping and lead solder are structures built after 1982 and before 1987.

c. Softeners and Other Point of Use (POU) and Point of Entry (POE) Devices:
Sampling sites with faucets that have POU or POE treatment devices, such as softeners, shall not be used as Tier 1, 2, or 3 sites unless insufficient Tiered sites are available. Field staff shall encourage water supplies to sample from a kitchen or bathroom tap that is not normally connected to the softener. If a sample of softened water is analyzed, then the water supply may consider returning to the same site to collect a sample of unsoftened water. Some residents may be able to bypass the softener at the tap. Both sample results (softened and unsoftened) will be used to calculate the 90th percentile. Sample results shall not be deemed improper on the basis that the water passed through a softener.

d. Supplies that bottle water:
An NCWS that is a water bottling plant and has fewer than 25 employees is classified as an NTNCWS, but all sampling under Act 399 is conducted at the raw water tap. All other sampling of the plant distribution system or bottling and packaging facility is done under the authority of the Michigan Department of Agriculture and Rural Development under Section 17 of Act 399, MCL 325.1017.

3. Monitoring Requirements

a. Summary of Rule Requirements:
The required number of distribution system sites is based on the population served. A water supply may sample more than the required number in a monitoring period. Supplies with fewer than five taps, must sample 100 percent of taps typically used for human consumption.

b. Monitoring Period:
Annual and triennial monitoring is conducted during the months June through September unless an alternate four-month period is designated.

c. Insufficient Number of Samples Collected:
When fewer than the required number of samples are collected, field staff issue a monitoring and reporting (M/R) violation and calculate the 90th percentile based on available data. To return to compliance with monitoring requirements, field staff should direct the water supply to monitor again in the next available monitoring period – next six-month period, for those supplies on a six-month frequency, or next calendar year, for those supplies on reduced monitoring. Establish the next due date based on the return to compliance date and the previously assigned frequency.

d. Improper Sample:
Samples deemed improper are not used to calculate the 90th percentile. A water supply may deem a sample improper by not submitting the sample to the lab for analysis. Once a sample is analyzed, only the field staff may deem a sample improper with approval from the:
   i. Community Drinking Water (CDW) Unit Chief and notification of the Field Operations Section Chief, for CWSs, or
   ii. Noncommunity and Private Drinking Water Supplies (NPDWS) Unit Chief approval and notification of Environmental Health Section Chief for NTNCWS.

To deem a sample improper, field staff investigates all samples collected in the monitoring period and analyzed. The investigation includes a review of documents that demonstrate compliance with monitoring and testing requirements (for example, the Instruction Sheets that are completed by the resident). Extended stagnation is not a sufficient reason to deem a sample improper. Encourage water supplies to select sites that are in regular use. The supply may collect a replacement sample for a sample deemed improper provided the monitoring period has not ended.

e. Reduce Monitoring for Only One Contaminant:
Monitoring cannot be reduced for only one contaminant. The monitoring frequency is the same for both lead and copper, except under partial waiver provisions. To date, field staff have not granted full or partial waivers under Rule 710a(7).

f. Reduced Monitoring When Copper Exceeds AL:
Reduced monitoring is allowed in the rule when the copper 90th percentile exceeds the AL, provided the lead 90th percentile meets the AL after optimizing CCT under Rule 710a(4)(d)(ii) and (iii). However, the DEQ believes that a supply with a copper AL exceedence should remain on a six-month frequency for both lead and copper and will not reduce the monitoring frequency when an action level is exceeded.

4. **Calculate Compliance**

a. Summary of Rule Requirements:
Steps to calculate the 90th percentile are listed in Rule 604f(1)(c). When fewer than the required number of sample results is available, the 90th percentile is calculated based on the available data. When five samples are collected, the 90th percentile is the average of the highest and second highest concentrations. When fewer than five

samples are collected, the sample result with the highest concentration is the 90th percentile.

b. All Samples Analyzed Are Used to Calculate 90th Percentile:
All samples collected and analyzed within the monitoring period are used to calculate 90th percentile. However, samples deemed improper or invalid, even if analyzed, are not used to calculate the 90th percentile.

c. Samples Collected Outside Monitoring Period
Samples taken outside the monitoring period are not used to calculate compliance. However, one exception exists – when a sample is deemed invalid and the supply has too few samples to meet the minimum requirements, the supply collects a replacement sample not later than 20 days after the date the sample was invalidated or by the end of the monitoring period, whichever occurs later, as allowed in Rule 710a(6)(d).

d. Multiple Samples From Same Site:
Multiple samples collected from the same site during the monitoring period are all used to calculate the 90th percentile (do not average the multiple results). Samples collected outside the monitoring period are not included in the 90th percentile.

5. Corrosion Control

a. Equivalent Corrosion Control Steps:
At this writing, CWS have used CCT steps as per rule rather than equivalent activities. Under Rule 604f(2)(b)(ii), a water supply may be considered by field staff to have optimized CCT if the supply demonstrates to the satisfaction of field staff that it has conducted activities equivalent to the CCT steps applicable to the water supply under Rule 604f(3). This determination is on a case-by-case basis after field staff have consulted with the water treatment specialist for CWS or the NPDWS Unit Chief and staff for NTNCWS. Field staff provide the supply with written notice explaining the basis for its decision and specifies entry point OWQPs.

b. Modification of DEQ Treatment Decisions:
Under Rule 604f(3)(h), the DEQ may modify its optimal CCT determination based on its own initiative or in response to a supply's proposal to modify existing treatment or OWQPs under Rule 604f(3)(g). Each revised determination is made in writing, sets forth the new treatment requirements, explains the basis for the decision, and provides an implementation schedule for completing the treatment modifications.

c. Change in Treatment or Addition of a New Source:
Water supplies are required to notify field staff of an upcoming long-term change in treatment or the addition of a new source under Rule 604f(2)(b)(iii)(C), Rule 710a(4)(d)(vii), and Rule 710a(7)(d)(iii). Field staff may require the water supply to conduct additional monitoring or take other actions to ensure that CCT remains optimized. If the water quality and characteristics of the new source are similar to the

supply's existing sources, then field staff may consider the new source as not adversely affecting the supply's CCT and no further action is needed.

6. Consecutive Systems (CS)

Systems must monitor as per rule based on their population. On a case-by-case basis, the DEQ may consider the entire combined distribution system of consecutive systems when establishing monitoring requirements.

a. Consecutive System Approach:
Some CS own their distribution system, but essentially have no water department. These CS purchase water retail and rely fully on the seller to provide all services including monitoring, operation, and maintenance of the distribution system. The combined distribution system (CDS) is considered one system for the purpose of complying with this rule.

b. Modified Consecutive System (MCS) Approach:
Some CS own and operate their distribution system. These CS purchase water wholesale and may rely on the seller to provide certain services through a variety of arrangements and agreements. The entire CDS is treated as one system for the purpose of determining the total number of lead and copper distribution system sites and WQP distribution system sites.

The U.S. EPA allows states to propose Modified Consecutive System (MCS) monitoring protocols for these large combined distribution systems (CDS) subject to U.S. EPA approval on a case-by-case basis. Field staff should work through Lansing central staff when proposing an MCS for a particular group of supplies to ensure consistent implementation among districts and with the U.S. EPA.

c. MCS General Requirements:
   1. The entire combined distribution system (CDS) is treated as one system for the purpose of determining the number of lead and copper tap samples. The total CDS reduced number of sites must be greater than or equal to the reduced number of sites for an individual system of equal size under Rule 710a(3).
   2. The number of lead and copper distribution system sites required in each consecutive system (CS) is based on percent of population of the CDS. Each CS collects no fewer than five samples.
   3. Each CS demonstrates compliance with sample site selection, lead and copper ALs, and monitoring requirements in the distribution system. In some wholesaler/CS arrangements, the wholesale system may agree to coordinate the collection of the samples, but the CS is responsible to comply.
   4. A CS may reduce the number of sites to no fewer than the reduced number for an individual system of equal size under Rule 710a(3). In most cases a CS is not eligible to reduce the number of sites, even if the CDS is able to reduce. The MCS number of sites is usually already lower than the reduced number for an individual system of equal size.

5. A CS that exceeds an AL returns to standard number of sites for a system of equal size until both ALs are met in two consecutive six-month monitoring periods. Reduced monitoring may apply, including accelerated reduced frequency under Rule 710a(4)(d)(v). The CS may resume MCS monitoring under the CDS protocol when the CS frequency matches that of the CDS (for example, the CS may rejoin the CDS that samples triennially, when the CS qualifies for triennial monitoring).
6. The MCS approach also extends to WQP because the purpose is to look at the entire CDS.
   (a) The numbers of distribution system sites are based on the population of the CDS. However, no minimum number of distribution system sites is required in any single CS in the CDS, provided the entire CDS meets the number of sites required. Selection of WQP distribution system sites should represent the entire CDS.
   (b) A CS that exceeds an AL must also monitor the following, if not already doing so:
      - WQP distribution system monitoring: A CS that is already monitoring for WQP in the distribution system at a reduced number of sites is not required to increase to standard number of sites unless the CDS is required to do so. However, if a CS is NOT already monitoring WQP in the distribution system and they exceed an AL, the CS must monitor WQP at the standard number of sites until both ALs are met in the most recent round of sampling.
      - Entry point monitoring: WQP and entry point lead and copper samples must be collected at each entry point that serves the CS (that is, the entry point at the treatment plant, not at the consecutive connection). In order for the wholesale supply (treating/selling supply) to perform this monitoring, the CS must inform the wholesale supply that the CS exceeded an AL.
      - Medium or small CDS monitor WQP only in monitoring periods that exceeded an AL. All large CDS monitor WQP, regardless of lead and copper levels.
      - Failure to maintain OWQP at the entry points (for all large supplies and for small and medium-sized supplies that exceed an AL after installing CCT) are excursions as outlined in Rule 604f(3)(f). An excursion is a treatment technique violation.
7. A CS that exceeds the lead AL is responsible to issue PE and to replace lead service lines as per rule.
8. The wholesale supply complies with requirements associated with CCT.

PROCEDURES:

WHO	DOES WHAT
Field staff, except as listed below	Make determinations and recommend actions requiring supervisor approval.
CDW Unit Chief for CWS or NPDWS Unit Chief for NTNCWS	Review and approve field staff's designation of improper sample.
Water treatment specialist for CWS or NPDWS Unit Chief and staff for NTNCWS	Consult with field staff as field staff determine on a case-by-case basis whether a water supply has optimized CCT using equivalent CCT steps.
CWS field staff	Work with CDW Unit staff when proposing an MCS monitoring protocol.
CDW Unit staff	Coordinate with U.S. EPA to receive approval on a case-by-case basis for MCS monitoring protocol.

SWTR - log removal for legionella as with crypto? Legionella

Benzie, Richard (DEQ)

From: Benzie, Richard (DEQ)
Sent: Wednesday, March 11, 2015 7:33 PM
To: Shekter Smith, Liane (DEQ)
Cc: Busch, Stephen (DEQ); Prysby, Mike (DEQ)
Subject: RE: Information Request and Documentation

Liane,

Steve's initial response is below.

As I see it, we need a plan of action fast.

1) Inform DEQ management, including legislative and media liaisons; suggest additional communication with DCH
2) Prepare response to Genesee County email – did anyone in ODWMA or DEQ have any contact with Genesee County about Legionella and if so, when and what? Was anyone in ODWMA or DEQ requested to meet with Genesee County to discuss Legionella and if so, when, and did they "decline" to meet?
3) Contact Flint to alert them of County's concerns and determine their response to the January 27th FOIA request.
4) Arrange for a meeting with Genesee County and other parties as deemed appropriate by DEQ management – DCH, Flint, Governor's Office, etc.; Establish a "Lead" agency but also develop a team approach to move forward and determine an appropriate, common message as well as when such information should be shared and by whom. Determine how long has Genesee County, DCH, and Flint been aware of the increased cases of Legionella and what the message should be about delays in public notification.
5) Determine additional steps – possible monitoring protocols, premise plumbing treatment options, public precautions if any, etc.; Consider possible CDC assistance.
6) Determine if EPA will be willing to share their draft Legionella guidance document being developed by a workgroup consisting of EPA, the States of Ohio, Minnesota, Pennsylvania, Washington, Nevada, Missouri and Nebraska, and CDC. The guidance will characterize the effectiveness of treatment technologies to address Legionella and address relevant regulatory implications. The primary implication is that individual customers that install "secondary" treatment systems to remove, reduce or prevent Legionella in their premise plumbing (such as hospitals are already doing) become by federal definition, public water systems required to comply with all applicable requirements of the Safe Drinking Water Act. The guidance has been delayed by internal reviews at EPA, but they are hoping to be able to have a final document in summer of 2015.

That's all I can think of at this point. Let me know what you think.

From: Busch, Stephen (DEQ)

To: Prysby, Mike (DEQ); Benzie, Richard (DEQ)
Subject: RE: Information Request and Documentation

Mike,

I am not aware of a meeting request from Jim Henry or the Genesee County Health Department as indicated in his email below. Did you receive any such request?

The FOIA is specifically directed to the City of Flint not the DEQ. If requested some of the information asked for regarding Total Coliform and E.Coli compliance sampling could be provided, but there may also be additional construction repair sampling data.

We can respond to Jim when you get back in, but at this point while the change in source may have created water quality conditions that could provide additional organic nutrient source to support legionella growth, there is no evidence or confirmation of legionella coming directly from the Water Treatment Plant or in the community water supply distribution system at this time.

> **Subject: Information Request and Documentation**
>
> Hello everyone,
>
> The Genesee County Health Department has made several written and verbal requests for specific information since October, 2014, including a Freedom of Information Act Request on January 27, 2015. The information still has not been received and the city's lack of cooperation continues to prevent my office from performing our responsibilities.
>
> The Genesee County Health Department has the responsibility to conduct illness investigations and consider all potential sources, this is not optional. In 2014, Genesee County experienced a significant increase of confirmed Legionella illnesses relative to previous years. Legionella can be a deadly, waterborne disease that typically affects the respiratory system.
>
> The increase of the illnesses closely corresponds with the timeframe of the switch to Flint River water. The majority of the cases reside or have an association with the city. Also, McLaren Hospital identified and mitigated Legionella in their water system. This is rather glaring information and it needs to be looked into now, prior to the warmer summer months when Legionella is at its peak and we are potentially faced with a crisis.
>
> This situation has been explicitly explained to MDEQ and many of the city's officials. I want to make sure, in writing that there are no misunderstandings regarding this significant and urgent public health issue. The Trihalomethane issues "pale in comparison" to the potential public health risks of Legionella.
>
> I am submitting the attached FOIA request again and requesting that the legal obligations of the request are met. If the information is not available, please let me know. In the past, I have requested to meet with the water plant staff and MDEQ regarding Legionella concerns. I did not receive a response from the water plant staff and MDEQ declined. I think it is in the best interest for all stakeholders that we meet and discuss the issues.

> Respectfully,

Optimization and Maintenance of Optimal Corrosion Control Treatment

Preliminary Assessment

U.S. EPA Flint Task Force

11/24/2015

DRAFT

1.0 Overview

The United States Environmental Protection Agency (EPA) has offered, and the City of Flint has accepted, the assistance of EPA experts on corrosion and corrosion control. This preliminary assessment is intended to document the activities and funding necessary to enable EPA to provide advice and support to the City of Flint in optimizing and maintaining corrosion control treatment under current water quality conditions as well as during and after the upcoming transition to the Karegnondi Water Authority (KWA) pipeline.

[Note: There are many other communities scheduled to transition from their current water sources to the KWA pipeline. Although the source water will be the same for the City of Flint and all communities transitioning to the KWA pipeline source, the intended treatment planned for these communities may differ and the studies undertaken for the City of Flint may or may not be suitable for use by the other communities. It is strongly recommended that the EPA Task Force discuss with the Michigan Department of Environmental Management (MDEQ) the importance of actively working with these additional communities to ensure that proper studies on optimizing and maintaining OCCT are undertaken prior to putting the new KWA source in service for all affected communities. If such studies are not currently underway, they should be initiated as soon as possible.]

2.0 Information Request

In order to provide effective advice and assistance, the EPA Task Force should request the following information from the City of Flint.

2.1 Current inventory of homes with service line information in excel or similar format.

Pipe loops are corrosion control treatment assessment tools that enable evaluation of the effects of potential water quality changes and different levels of orthophosphate treatment on the existing pipe scales in order to select the most effective treatment before the treatment is applied on a city-wide basis. The pipe loops utilize lead service lines that are actively in service and carefully extracted so that the treatment assessment is conducted with pipes that represent conditions within the distribution system. As it would not be possible to perform service line extractions in the winter without significantly altering or dislodging the scales within the pipes, the identification and extraction of lead service lines should be given the highest priority to ensure that a sufficient number of lead pipes can be identified and extracted as soon as possible. In order to identify suitable homes with lead lines, the EPA Task Force will need current records on lead service line locations to be provided as soon as possible so that sampling can be coordinated and conducted to verify the presence of lead lines.

To minimize the need for excavation, homes with the longest lead service lines should be chosen so that multiple segments can be harvested from each lead line. The lead lines would typically be the longest where the water main is located across the street from the home and the home is set back on the property with respect to the street. An estimated 20 lead pipe segments should be carefully extracted and handled using ORD-specified procedures for use in constructing pipe loops at the treatment plant.

As the scales within the service lines have been subject to significant and iterative water quality changes in a relatively short period of time, it is also necessary to extract additional lead and non-lead portions of service lines to assess the current condition of the scales within the service lines.

2.2 All lead in water testing results for City of Flint, including those not used for Lead and Copper Rule compliance.

Studies have shown that homes served by lead service lines generally have much higher lead levels than homes without lead service lines. As it is anticipated that the City of Flint's service line records will be incomplete, the lead-in-water testing data is a supplemental tool that can be mapped to identify areas of the city that may have higher lead-in-water levels which would indicate the presence of lead service lines. This information will help the EPA Task Force in the identification and extraction of lead service lines for constructing the pipe loops and in identification of areas to test the progress of corrosion control.

2.3 Identification of areas in Flint with elevated blood lead levels.

Similar to the lead-in-water testing, identification of areas (e.g. Zip codes, neighborhoods) where blood lead levels have increased since the switch to the Flint River can provide additional data which would indicate the presence of lead service lines for the identification of areas to test the progress of corrosion control.

2.4 Addresses of homes that have had water service interruptions or street disturbances (e.g., water main breaks, road/sidewalk construction, etc.) within the last year.

Streets where there have been potential physical disturbances and homes where the water service has been interrupted should be prioritized for evaluation for the presence of lead service lines as the disturbances can release very high lead and prolonged stagnation can affect the stability of the scales within the pipes.

2.5 Addresses of currently unoccupied homes.

Similar to homes where the water service has been interrupted, homes that are unoccupied should be prioritized for evaluation for the presence of lead service lines as these homes may pose a significant risk to incoming occupants if the home has a lead service line. Recently unoccupied homes also may provide important evaluation locations of water usage impacts on scale stability and lead release exposure.

2.6 Identification of the pressure zones and location of each of the water quality parameter locations (addresses) within each pressure zone used for water quality parameter measurements (pH, alkalinity, orthophosphate, chlorine, total Coliform) in the distribution system, along with copies of the water quality parameter analytical results for past 4 rounds of monitoring.

In addition to corrosion control treatment optimization, the City of Flint must simultaneously comply with all other applicable National Primary Drinking Water Regulations (NPDWRs). A system-wide assessment of the water quality will provided information necessary to ensure that any potential issues with other NPDWRs can be identified and resolved. Information regarding the water quality in the distribution system is necessary to evaluate the stability of the water quality parameters throughout the distribution system, and to detect locations that may have the highest risk of lead release, TTHM formation, or the presence of microbial contamination.

3.0 Immediate Tasks and Timeline

The following tasks should be undertaken immediately (November/December 2015)

3.1 Determination on EPA funding commitment(s) (DRA).

3.2 Discussion with Central Regional Laboratory (CRL) regarding laboratory capabilities and support (GWDWB, ORD).

3.3 Development of EPA QAPPs encompassing the following activities (GWDWB, ORD, Others*):

- 3.3.1 Verification of presence of lead service lines*;
- 3.3.2 Pipe rig construction, operation, and maintenance;
- 3.3.3 Treatment assessment monitoring;
- 3.3.4 Evaluation of lead reservoirs within service lines; and
- 3.3.5 Evaluation of scale degradation due to stagnation events in unoccupied homes and water shut-offs*.

*If these activities are undertaken by one or more of the local partners, QAPP development should be part of the agreement.

3.4 Identification of local partners that can coordinate with the EPA Flint Task Force, MDEQ, and the City of Flint, and establishment of agreements to provide assistance on field and other activities (ORD).*
[Potential local partners that have expressed strong interest and willingness to collaborate with EPA include Wayne State University, University of Michigan Flint, Michigan State University, Hurley Medical Center, and Genesee County Health Department.]

3.5 Outreach and education – specifics to be determined.
[Potential local partners Hurley and WSU have asked ORD directly if EPA can provide training/education for their staff on lead in water occurrence, sampling for lead, and corrosion/corrosion control treatment]

3.6 Assessment of information from 2.3 to verify the presence of a sufficient number of accessible homes with lead service lines that can be extracted for construction of pipe loops and to evaluate the current state and stability of the scales within the lead and non-lead portions of service lines (TBD).

3.7 Extraction of approximately twenty lead line segments with active water for construction of pipe loops, and six additional full service lines with different pipe material (two with lead and galvanized iron, two with lead and copper, and two with lead and plastic segments) for analyzing the lead reservoirs within the lead and non-lead segments of the service lines (TBD).

3.8 Risk evaluation and communication on the potential risk from physical disturbances to lead service lines, reoccupation of unoccupied homes and re-establishment of water service following water shut-offs (TBD).

4.0 Funding Needs (To Be Determined)

5.0 Proposed EPA Assistance

The narrative below describes the scope of work to be undertaken in providing assistance to the City of Flint and is contingent on adequate funding being provided.

5.1 Lead Service Line Detection Methodology Development

Verification of the presence of lead service lines is necessary for identification and extraction of lead service lines, sampling for treatment assessment, Lead and Copper Rule compliance sampling, risk evaluation and implementation of a lead service line replacement program. Blood lead level (BLL) or other lead-related health evaluations also need to be able to identify all lead sources for blood-tested individuals to prioritize risk locations and mitigation strategies. This methodology development is designed to determine if a simple water sampling protocol can give a convenient means to verify with some level of confidence, whether or not a residence has a lead service line, through relatively non-intrusive water sampling. Experience with other utilities has shown that paper records may either under or overestimate the presence of lead service lines.

The strategy to be employed is based on published protocols with improvements being researched by Polytechnique Montreal (Michele Prevost, Elise Deshommes, Clement Cartier). This requires staffing for coordination with Flint paper records, resident contact, plumbing mapping, field sampling (TBD, but estimated at 20 locations with no LSLs for "control" purposes, and 50 locations believed to have LSL for validation. Development of this protocol could involve re-sampling to test techniques, and could utilize one or more Palintest electrochemical analyzers after validation vs. ICP-MS. EPA-ORD has one Palintest analyzer which can be used. Field personnel would work closely with R5 CRL to test the limits of analytical performance of the Palintest analyzer.

5.2 Corrosion Control Treatment Optimization Evaluations

The corrosion control treatment optimization evaluations are necessarily separated into two stages. The first stage is intended to optimize corrosion control treatment with the current water source and water quality conditions. The second stage is designed to prepare for the transition to the new water source (KWA Pipeline) and water quality conditions, and to ensure that the City of Flint is able to simultaneously comply with all National Primary Drinking Water Regulations following the transition to the new source.

5.2.1 *Short-Term (Current) Lead Release Optimization Evaluation.* A lead pipe rig system will be constructed at the Flint water treatment plant with exhumed lead pipes, carefully collected and installed into the pipe rig. EPA-ORD will provide technical assistance in the rig design and construction, as well as the design provisions for chemical additions. One to two people will be required to be on-site to perform periodic chemical analyses and operate and maintain the pipe rig system, as well as to troubleshoot/repair any problems and to collect samples. Laboratory instruments for pH and colorimetric tests (chlorine residual, orthophosphate) will be needed on site. It is anticipated that the design will include a "control" loop and loops with possibly 3-4 different dosages, in duplicate. The

estimated sampling frequency would be at least three times per week, using ICP for metals and ICP-MS for lead on each sample, with one complete characterization sample before each stagnation period. Filtration apparatus will also be needed.

5.2.2 *Simultaneous Compliance Optimization Pilot Testing Prior to Flint Water Plant Treatment of KWA Water*. This effort will necessarily be more expansive than the short-term evaluation. The same control pipes would carry over, but new pipes would need to be stabilized with the current water. Upstream of the lead pipe rig, there would need to be a series of jar tests or a small pilot plant established to optimize coagulation, softening (if necessary), filtration and disinfection processes to meet disinfection byproduct (DBP) limits and microbial inactivation requirements. Investigations are also needed to assess the potential impacts of different possible treated Lake Huron water qualities on chlorine, biofilm growth, water age, microbial pathogens such as Legionella, phosphate demand and scaling potential. Pilot evaluations would be done on different unit processes using anticipated Lake Huron water, using university-run pilot plants, shipped or trucked water, etc. Some pilot evaluation analyses could be done on-site with portable analytical instrumentation as is typical. When a final water quality target is determined, the target finished water would become the source water to feed into the lead (and metal) pipe rigs, and thereafter the optimization of phosphate dosing would be done on the stabilized exhumed lead pipes in the pipe rigs. A reservoir may need to be constructed to hold processed simulated Lake Huron treated water produced by the pilot plant and fed to the pipe rigs. This evaluation must be started as soon as possible to allow sufficient time for reliable results to avoid having to conduct full-scale testing on water delivered into the distribution system that could impact Flint consumers after the switch to the KWA pipeline is made.

5.3 Lead Source/Release Diagnostic Evaluation

While the data collected from the pipe loops can provide information on the relative effectiveness of various treatment schemes, conditions at the plant are not the same as within the distribution system. Continued monitoring of lead levels at high risk sites throughout the distribution system is needed to make any necessary adjustments based on actual conditions within the distribution system. EPA estimates that approximately 45 homes will need to be identified for ongoing sampling to inform the treatment optimization process. (15 with lead & copper service line portions, 15 with lead & galvanized iron service lines and if available, 15 with lead and plastic service line portions). This evaluation is necessary for determining what the relative contributions of lead are from different plumbing sources in order to assure optimization of lead and other metal release from the service lines and premise plumbing. Two sampling rounds are the minimum expected for profile sampling which will utilize small volume samples through faucet and sink area and larger (one-liter) samples thereafter. Sampling would involve 15 sites for each combination of plumbing materials (total of 45 sites), with an anticipated 10-15 sequential samples per site for metals per sampling event. Additional samples will be collected and analyzed to characterize the water quality and the sequential samples will be analyzed for Pb, Cu, Fe, Zn, and Al. An experienced plumber or researcher will be needed to map the plumbing at each site, field personnel will be needed to collect and ship samples, and a data manager will be needed to manage the data. If dissolved vs. total metals are desired in the analyses, an addition person with field filtration skills will be needed, in addition to the lab

supplies. If meters, brass or galvanized pipe are found to be a significant source of lead, those devices should be included in the pipe rigs.

5.4 Impact of Water Use/House Occupancy on Stability and Lead Release from Lead and Other Premise Piping.

There are a large number of unoccupied homes in Flint. Homes which have been unoccupied for an extended period of time can pose a greater risk to incoming residents due to the stagnation of water within the plumbing over an extended period of time which can destabilize the scales within the plumbing and release high lead levels into the water. If access can be facilitated by the City of Flint or other organizations involved with housing, sampling will be conducted at 10-20 vacant or recently occupied homes in conjunction with a flushing program to assess how long it takes for increased water usage to improve the effectiveness of the corrosion control treatment for these homes. Sequential sampling profiles would be done for metals as well as chlorine residuals for each home. Flushing for different times would be tested and evaluated with repeated profile sampling to see if there is any improvement in lowering lead levels with increased water use.

5.5 Protocol for Exposure Estimation Sampling for Health-Related Evaluations (Premise & Building Plumbing).

This protocol development would compare various potential options for sampling to estimate the cumulative metal exposure from the drinking water in premise plumbing or schools. Comparisons would be made with manual or automated proportional sampling, tap POU units that could log water use and be disassembled and digested for metal content, and random daytime sampling protocols. Different types of POU-suitable filtration apparatus would be tested to see if designs would permit quantitative separation of dissolved versus particulate lead and other metals. Support would be needed for setting up and operating test systems, analyzing virgin and exposed filter/device materials with accumulated metals, building and installation of proportional samplers or development of protocol for resident-collected samples, rapid turn-around Lead and other water analyses of test exposure water fed into experimental systems.

5.6 Risk communication on lead service lines

Request OEJ support/assistance for the development and dissemination of risk communication material on lead service lines, including the potential risk from physical disturbances to lead service lines and lead reservoirs in other pipes downstream of lead service lines.

5.7 Pipe analyses for long-term treatment assessment and mechanisms of lead and other metals release

Optimization of corrosion control treatment requires specialized knowledge on scale chemistry as well as specialized equipment and equipment operating skills. The timeline for activities related to evaluating the progress in optimizing corrosion control treatment following the transition to the KWA pipeline source will extend beyond the current fiscal year and likely well into FY 2017. The necessary resources and expertise must continue to be made available to the Task Force for the expected duration of the project in order to ensure a successful outcome

which would enable the City of Flint to simultaneously comply with all NPDWRs following the transition to the KWA pipeline.

6.0 Timeline

The proposed activities are contingent upon available funding. As such, it is not possible at this time to develop a meaningful timeline, with the exception of the activities in Section 2.0 and some of the activities in Section 3.0 which are discussed in those sections. Once funding is secured a detailed timeline will be developed that incorporates both funded and unfunded activities. A Task Force member will be identified as the lead person responsible for ensuring the completion of each activity or group of activities to ensure that the work is completed in accordance with the timeline.

DRAFT

ROWE PROFESSIONAL SERVICES COMPANY

Large Firm Resources. Personal Attention.℠

January 7, 2013

Mr. Edward Kurtz, Emergency Financial Manager
City of Flint
1101 S. Saginaw Street
Flint, MI 48502

Subject: Review of December 21, 2012 Presentation – City of Flint Water Supply Assessment

Dear Mr. Kurtz:

As requested, we have reviewed the analysis of water supply alternatives for the City of Flint which was presented to the State Department of Treasury by Tucker, Young, Jackson, and Tull, Inc. (TYJT) on December 21, 2012. Our review is attached and summarizes the primary differences between the TYJT assessment and our previous studies and provides explanations of why we believe there are differences.

We have also reviewed the options for continued DWSD supply included in the TYJT presentation. It is not clear whether these are presented as specific offers on behalf of DWSD or included as examples for analysis, but we have noted some items which we believe should be addressed and considered as these options are compared.

If there are questions, please contact me.

Sincerely,
ROWE Professional Services Company

James E. Redding, P.E.
Vice President / Director of Engineering

Attachment

R:\Projects\04C0105\Docs\Correspondence Out\January 7 Kurtz.docx

Review of TYJT December 21, 2012 Presentation
City of Flint Water Supply Assessment
Prepared by Rowe Professional Services Company

DWSD Supply (Slides 7 through 9)

1. The 8 mgd maximum day supply by DWSD options can result in periods during the summer when most of the water to meet demands will be supplied by the City from the river. To aid in maintaining a consistent water quality, softening of the water from the river should be provided with this option, greatly increasing the City's costs.

2. Upgrades to Flint's WTP and dams will be needed for options requiring blending, since the WTP will be required to provide continuous, reliable service and compliance with recent surface water treatment regulations.

3. The rates for the options analyzed are shown on Slide 9 as "TYJT Estimates". Options and rates shown are different than presented by DWSD previously.

	DWSD 11/29/2012	TYJT Estimates
18 mgd Maximum Day - P&B	$16.24	$16.37
12 mgd Maximum Day - P&B	$16.30	$16.31
8 mgd Maximum Day -P&B		$12.68
12 mgd Maximum Day - Imlay	$14.38	$14.38
8 mgd Maximum Day - Imlay		$11.11

4. Since the rates used in the analyses are shown as estimates, are they actual offers or just presented as "what if" scenarios?

5. We assume that the Imlay options are based on transfer of the 72" main through Lapeer County to Flint. The analyses show a capital cost of $4.7 million; we assume that this is the proposed purchase / lease cost to Flint. This should be clarified along with pertinent details.

6. If the transmission main is transferred to Flint, what are Flint's responsibilities regarding service to the Lapeer County customers? If they remain DWSD customers, then Flint should receive some revenue for the use the main. It does not appear this is included in the TYJT analyses.

7. If the transmission main is transferred to Flint, we assume that the city will be responsible for the maintenance of the 50 year old main. The TYJT analysis did not include this.

8. Do the rates shown include the credit for "reliability" which had been discussed with DWSD?

9. If the point of commerce is changed from Baxter and Potter to Imlay, a new meter pit will be required. The cost of this does not appear to be included in the TYJT cost analyses.

Flint River Supply (Slide 10)

1. If any of the "blending" options are chosen, it will be necessary to upgrade the Flint WTP and dams to provide reliable, continuous service and compliance with recent surface water treatment regulations.

Data Collected (Slide 14)

1. The slide notes that Flint blending is based on DWSD supplying 2/3 and Flint supplying 1/3 of 12 MGD ADD. For the maximum day demand (18 mgd), if DWSD supplies a maximum of 8 mgd, Flint will supply 10 mgd or 56% of the total. However, such a large portion will make it more difficult to blend and achieve consistent water quality. Flint will need to soften water for these options.

Benchmarking Comparisons (Slide 16)

1. The slide subtitles are "KWA O&M Inflation Factor" and "DWSD and Flint Rate Inflation Factor". It seems appropriate to benchmark O&M costs for the KWA, because future costs of service will be dependent on how operating costs are impacted by inflation. For Flint, it does not seem appropriate that "rate inflation" from other utilities be used to determine the impact of inflation on future cost of service. Rates are impacted by inflation, but also by other factors such as debt and customer base. O&M expenses and rates are different and care should be exercised not to mix the two during analyses. The TYJT analyses apply an inflation factor (based on rates from other utilities) to the Flint WTP operating expenses, which does not seem to be consistent.

2. The KWA will supply raw water; SOCWA and YUCA both supply finished water. Regulations impact the O&M for finished water suppliers but should not impact the KWA O&M. The use of data from SOCWA and YUCA does not seem like a comparable comparison with the KWA. Finished water suppliers will have increased costs due to regulatory compliance, which really are not due to "inflation" of the costs of wages, power, chemicals, etc.

3. DWSD has a history of rates to Flint and other suburban wholesale customers. Rates tend to be quite specific to each utility, based on much more than just the costs of operating and maintenance. It appears that DWSD historical rates have not been considered in projecting future DWSD rate increases.

Capital Financing (Slide 17)

1. KWA bonds are planned to be general obligation bonds, backed by member counties.

O&M Inflation Factor (Slide 20)

1. SOCWA and YUCA are finished water suppliers; ever-changing regulatory requirements will impact their operating costs more than a raw water supplier, such as KWA.
2. KWA will be a supplier of raw water. O&M costs should primarily be limited to power and labor, with a little chemical use for zebra mussel control. KWA will not provide treatment of the water.

3. The KWA study assumed power, labor, and chemical costs increase at an annual average of 3%. TYJT indicated this is too low and suggested 5%.

4. Following are examples of historical inflation, which support the 3% as a reasonable assumption for O&M expenses (not rates)
    a. Labor- GCDC-WWS labor costs have increased at an annual average rate of 2.5% since 2003
    b. Electricity Rates in Michigan (per U.S. Energy Information Administration) have increased an average of 3.2% since 1999.
    c. The U.S. Bureau of Labor Statistics indicates that the inflation rate over the last 30 years has been an average of 2.8%.

Finished Water Rate Inflation (Slide 21)

1. TYJT bases their assumptions for rate inflation on a survey of rates from three other water suppliers, but ignored the actual rate history of DWSD. TYJT assumed DWSD rate increases of 4.4% annually (if water is purchased from P&B) and 2.9% annually (if water is purchased from Imlay). Based on the actual charges by DWSD to Flint, DWSD historical rates are as follows:
    a. 10 year increase in DWSD rates to Flint:: 10.5% annually
    b. Average annual increase through 45 year history: 6.7%

2. Note that for the KWA analyses, an inflation factor has just been applied to power, labor, and chemicals. Although higher prices for labor, power, and chemicals impacts utility rates; rates are impacted by many other factors, many of which are not related to inflation. Rate inflation will likely be different than O&M inflation. Other factors impacting rates:
    a. Debt – the amount of debt varies widely between utilities
    b. Number of customers / quantity of water sold – there are many fixed expenses with a utility, that if are distributed amongst more users/more gallons sold will result in lower rates. Conversely, if there are fewer users or less water sold, the rates are higher. Assumptions regarding future water consumption will have a great impact on "rate inflation".

3. Unlike KWA and Flint operating expenses which will increase over time based on inflation, the cost of continued DWSD service should be based on the inflation of DWSD rates, to include the increasing cost of other DWSD expenses such as debt and the impact of reduced customers / demands in addition to increasing O&M expenses.

4. Even though there could be a one-time reduction in DWSD rates through adopting the model contract, limiting peak demands, and or changing the point of commerce; it doesn't seem reasonable to assume that subsequent annual increases will only average 4.4% through the 30 year period of analysis. This is significantly less than historical performance (yet TYJT suggests that inflation for KWA O&M expenses will increase at almost double the rate of historical indicators).

Capital Financing with Revenue Bonds (Slide 24)

1. Note that the KWA bonds will be general obligation bonds backed by the member counties.

2. The 2009 KWA Study assumed 6%, 25 year financing. The interest rate for planning was reduced in the 2012 Study update to 5%, which is still higher than if bonds were sold today.

3. Financial consultants determined the charges for purchasing capacity in the KWA supply based on the estimated project cost plus appropriate financing costs. Based on 60 units of capacity, $538,764,000 will be generated for repayment of debt and project costs using the capacity charges in the KWA capacity agreement.

25 years * 60 units * $355,300 / unit =	$532,950,000
3 years * 60 units * $32,300 / unit =	$ 5,814,000
	$538,764,000

4. For a KWA project cost of $272,421,558, total P&I is $483 million. The difference of $55,500,000 is available for financing expenses (capitalized interest, bond issuance costs, etc.) and additional contingencies.

5. Bond holder reserve is not a requirement for general obligation bonds.

6. TYJT assumed that 3% interest would be earned on the bond holder reserve during the 25 year bond period. Current interest rates are less than 1% and it seems inappropriate to assume such a high rate will be earned on retained funds.

7. Bondholder reserve, if provided, should be applied against the last couple of P&I payments. The TYJT did not apply it. This will reduce their project costs.

KWA Construction (Slides 26 through 29)

TYJT has indicated that the KWA construction cost estimate is too low. The primary differences in cost estimates for the project appear to be the following components:

1. Pump Stations (Slide 27) – The TYJT estimate for the pump stations is more than double that used by the KWA ($54,573,314 vs. $24,618,080). KWA estimates were based on actual construction costs from recent projectd completed by Genesee County within the last eight years.
   a. 32mgd water pump station including two-10 MG ground storage tanks - $13.4 million
   b. 80 mgd wastewater pump station, 50 feet deep wetwell – $8.3 million
   c. 30 mgd wastewater pump station, 50 feet deep wetwell – $9.4 million

   The KWA budgeted amount seems reasonable for two pumping stations as currently planned and to be constructed in rural areas (not southeast Michigan).

2. Redundant Power – There is no need for redundant power; other provisions will provide reliability of supply.

3. Land – Preliminary engineering has continued so earlier budgets established for planning for land acquisition can be greatly reduced. Options have been obtained on all properties which must be

purchased, so purchase prices are known. It will be necessary to obtain easements for only two miles of pipeline construction. All land costs are now estimated at $1.25 million.

4. Engineering, Legal, Administration & Contingencies
   a. The October 2012 KWA estimate provided an allowance of 25% of construction cost to cover engineering, legal, administration, and contingencies (ELAC). This was reduced from the 38% allowance used in the 2009 Study because ongoing planning and design have firmed up many of the details of the project, including:
      i. The intake design has been completed and all regulatory permits obtained.
      ii. The transmission main route has been determined. Meetings with road agencies have firmed up the requirements for construction and restoration within rights-of-way. Environmental review and permitting are in process.

   b. TYJT costs for Intake Crib, Pump Stations, and Transmission Mains (Slide 30) include a 30% allowance for ELAC. These allowances (from Slides 26 through 28) total $72,139,566. In addition, Slide 30 provides the following additional ELAC costs in the project total:

Design Engineering / Pump Stations	$16,939,581
Construction Management	$14,434,410
Administration	$ 349,440
Legal	$ 831,000
Total	$32,554,431

   c. Combining this with the $72,139,566 totals $104,693,997 or 43% of the estimated construction cost. We believe that such a high allowance for ELAC is not appropriate for a project of this magnitude where preliminary engineering and some design have already been completed.

Cost Comparison (Slide 30)

1. The TYJT pump station price is too high based on costs of similar projects; costs used by KWA are based on costs of recent local projects. The KWA estimate is believed to be sufficient for the proposed pumping stations.

2. Redundant power is not required; this does not need to be included in the TYJT estimate.

3. Land for LHPS – actual price is $360,000

4. Design Engineering / PS and Transmission – KWA included engineering in the 25% ELAC allowance included in the $207,752,895 estimated cost of transmission mains; TYJT included engineering in their 30% ELAC allowance included in the $218,811,559 estimated cost. By adding $16,939,581 for design engineering, $14,434,609 for construction administration, $349,440 for administration, and $831,000; it seems that ELAC is being "double-counted". The TYJT 43% allowance for ELAC seems unwarranted for a project with a great deal of preliminary and design engineering completed. The 25% KWA allowance is believed to be sufficient.

5. Easements and land (other than LHPS) should total $1,140,000, based on current options and specific needs for easements.

Other Considerations – Redundancy / Reliability (Slide 33)

1. Unfunded Mandates/ Future Regulations
    a. The proposed KWA supply will deliver raw water; it is not anticipated to be affected by future changes to regulations. Regulations will impact the City of Flint with respect to treatment and/or distribution of finished water. The City will be subject to these requirements with any of the DWSD blending options, just as they will be responsible for them if supplied by KWA. Some compliance costs may actually be less with the higher quality Lake Huron water rather than Flint River water as the source.

2. State Goals
    a. The TYJT presentation indicates that creation of a new raw water supply is contrary to the governor's goals as suggested. However, the development of a new raw water supply provides new opportunities. Communities in Sanilac, St. Clair, and Lapeer counties will have the option to join a regional water supply and replace their small local supplies where limited supplies and high concentrations of arsenic have been a concern. The new water supply also provides great economic development opportunities. The raw water supplied by KWA will make a new commodity, raw water, available to the region. A large, low-cost supply of raw water can be a valuable resource for industries and agri-businesses. The development of a new water supply will also create construction jobs through the short term period of building the new water supply and subsequently over a longer period as new businesses and industries are developed in the area.
    b. The City of Flint and area communities will benefit as permanent jobs are created for operating and maintaining the local treatment facilities.

3. Redundancy
    a. We agree that the KWA and DWSD options are similar with respect to redundancy. Both provide the primary water supply; customers are responsible for their backup supply.

Other Considerations – Cost Slide 34

1. TYJT indicates that the DWSD 8 mgd supply option is the least cost alternative.
    a. The TYJT analysis does not include the cost of needed upgrades to the City's WTP or increased operating costs in their analysis. During summer months, water from the river will need to be softened before blending. More than half of the water supplied will be provided from the river. When the cost of upgrades to the WTP and the increased operating costs (for softening) are added to the TYJT analysis, the KWA option is less than the DWSD 8 mgd option.

2. For any of the DWSD "blending" options, upgrades will need to be made at the WTP to provide for continuous, reliable operation and compliance with new surface water treatment rules. Increased capital and operating costs for treating water from the river should be added to the TYJT costs for comparison with the other options.

3. Water from the river will require greater effort to treat than water from Lake Huron (more chemicals, power, and residuals). The TYJT analysis shows about the same O&M costs for the Flint WTP, regardless of water source. It seems that the WTP O&M costs for the KWA options should be reduced to reflect the savings from treating Lake Huron water.

4. The TYJT presentation noted that the KWA analysis did not include allowances for mechanical and process improvements within the planning period. The KWA will supply raw water. The facilities consist of pipe, pumps, and a tank. There are no treatment facilities which would be susceptible to future regulatory changes. The only improvements that seem likely would be the need to provide additional capacity. Capacity expansion is planned to be financed through capacity charges to new users.

5. The provision for redundant connections between the City's water system and the GCDC system was included in the most recent water supply agreement between the two, in 2011. Although not a KWA cost, the cost of the redundant connections should be considered with all options.

6. The $2.3 million budgeted for land by KWA was intended to cover all land requirements. Since the October update, options have been obtained on all land to be purchased and the locations of easements needed has been finalized. Total land costs are now estimated to be about $1.5 million.

7. The 2004 study included a 47% allowance for engineering, legal, administration, and contingencies (ELAC). The 2009 study reduced the allowance for ELAC to 37% because many of the details since the 2004 conceptual study had been better defined. For the October 2012 update, the allowance for ELAC was reduced to 25% because continued planning and preliminary engineering further addressed details from the earlier concepts.
    a. The detailed design (plans and specifications) and permitting have been completed.
    b. The transmission main route has been finalized. Meetings with road agencies have established requirements for construction and restoration within road rights-of-way. Environmental permitting is in process. The primary remaining unknown is pipe sizing, which is largely dependent on Flint's participation.

    It is our experience that the 25% ELAC allowance is appropriate for a project of this magnitude at this stage in the planning / design stage. The 43% ELAC allowance recommended by TYJT is excessive for a project in the design phase.

8. Flint's WTP as a backup to the KWA will be less difficult to provide for than the current arrangement as a backup to DWSD. We believe there is potential for challenges with chemistry and treatment for the proposed DWSD blending options, too.

9. It doesn't seem that oversizing the KWA capacity is a good solution for the city's water loss problems, if that is what is being suggested.

10. Yes, it would be nice if the KWA system could be constructed to firmly determine its cost and time to complete before making a decision about water supply alternatives. However, a decision is needed regarding Flint's participation so that the sizing and design can be completed, before it can be built.

Project Costs - TYJT Slides 26 through 30

	KWA	TYJT
Intake and Crib		
Construction	$22,076,850	$22,076,850
ELAC	$5,519,213	$5,519,213
Property	$2,300,000	$2,300,000
Pumping Stations		
Construction	$24,618,080	$54,573,314
Land		$75,000
ELAC	$6,154,520	$16,394,494
Transmission Mains		
Construction	$166,202,316	$167,419,530
ELAC	$41,550,579	$50,225,859
Easements		$1,166,170
Engineering		
Design Engineering		$16,939,581
Construction Management		$14,434,609
Administration		$349,440
Legal / Easements / Contracts		$831,000
Power	$4,000,000	$4,000,000
Redundant Power		$1,273,200
Total Construction	$212,897,246	$244,069,694
Total ELAC	$53,224,312	$104,694,196
Total Land / Property / Easements	$2,300,000	$3,541,170
Total Power	$4,000,000	$4,000,000
Total Redundant Power	$0	$1,273,200
Total	$272,421,558	$357,578,260
ELAC as % of Construction	25.0%	42.9%

		20.9%			19.2%	

Notes:

Engineering Fees include all planning, soils investigation, design, construction inspection & testing, and construction management costs
Engineering Fees % is based on final construction cost
Engineering and Contengency % is based on engineering fees + amount final construction cost exceeds estimate
Final Construction Cost % is based on difference between final construction cost and engineer's estimate
NEES Project Contractor went out of business during project - increasing cost to finish project
Projects constructed within last ten years

Introductions

Purpose - Dillon
- To advise Gov on what is the best financial interests of Flint
- has battle of experts in front of him
- wants DEQ to be "umpire"
- consider other communities (Tonka Lapeer)
- still mentioning agricultural benefit?

ET - very passionate

Ambrose - Finance Dir - city
- says time is past to make decision
- city says KWA is best vs best proposal from DWSD (3rd time DWSD has given Flint proposal)
- city will save $100 - $300M over 20 yrs
- even with cost overruns & const/delays
- doesn't want Flint to be "island"
- may allow county to consolidate city operations - further future savings
- Day after Flint Council passed resolution to go to KWA DWSD issued releases trashbashing proposal + denigrating KWA's engineering estimates

- Jeff Wright
- Cost overruns charges to Flint if they delay decision - to join is the cost of "redesign" + cost of delay?
- Plan to start intake this year w transmission mains to be constructed in 2014

Dillon - wants to make recd to Governor tonight or today - KWA

Jeff Wright
- Co has pledged full faith & credit so city does not have to
- If revenues were insufficient to pay bonds the County could "assess" residents/users to make up needed revenues.

TYJT - dispute the claim that their ELAC is too high

Pump Stations

Land costs - Co/GWA spent $590,000 while TY Report says it will be $27M

Also - Detroit area labor costs - 20% greater than Flint area (geographic differences)

TYJT - DWSD proposals may be different than what Flint has seen
- An option - 36" second line to be built (twin) that would be paid for by all customers pro rated on usage?
- But proposals haven't been presented to city

DWSD staff

- 1st issue - sense of cost
  - discrepancy(ies) on ELAC, PS, etc.
  - overruns / contingencies
  - who's best to determine that?
  - will give Treasurer's opinion

2nd - Flint River issues → will give opinion - other uses, NPDES, etc.

3rd issue - impact on others
does that involve others or is it Flint's problem.

TYJT - need to get the formal offer to FRA for constructing 2nd pipe (36")
- impacts to others in DWSD

Mitonish → leave

Mayor of Flint
- west of RWA to best of DWSD
  - should be best to best or worst to worst
